LM2780
Ultra-Low Ripple Switched Capacitor Voltage Inverter

General Description
The LM2780 is a charge pump that inverts an input voltage in the range of 1.8V to 5.5V to the corresponding output voltage of -1.8V to -5.5V. With use of three or four low-cost external ceramic capacitors, the LM2780 can provide up to 50mA of output current.
The LM2780 operates at a 12kHz typical switching frequency to minimize supply current (60µA typ.). Two charge pumps operate 180° out of phase to significantly reduce the output voltage ripple compared to that of traditional single-phase charge pump circuits. If larger output ripple can be tolerated, optional capacitor C2 may be omitted to reduce the cost and size of the solution. The LM2780 is available in an 8-pin Micro SMD chip-scale package.
See also: LM2781, a fast clock (210kHz typ) version of this topology with even lower output voltage ripple.

Features
- Inverts Input Voltage
- Ultra-Low Voltage Ripple and 8Ω Typical Output Resistance with Two Flying Capacitors
- Output Resistance of 18Ω Using One Flying Capacitor
- 12kHz (typ.) Switching Frequency
- 8-pin micro SMD Package (1.4mm x 1.4mm x 0.5mm)

Applications
- Cellular Phones
- Pagers
- PDAs
- Op-Amp Power Supplies
- Interface Power Supplies
- Handheld Instruments

Typical Application Circuit

**Absolute Maximum Ratings** (Notes 1, 2)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

- **V\text{IN}** pin: Voltage to GND -0.3V to 5.8V
- **SD** pin: Voltage to GND \(-0.3\text{V} \) to \((\text{V\text{IN}} + 0.3\text{V})\), with 5.8V max

Output Short-to-GND Duration (Note 3) 1 sec.

- Maximum Junction Temperature \((T\text{J-MAX})\) 150˚C
- Storage Temperature Range \(-65˚C \) to \(+150˚C\)
- Pad Temperature (Soldering, 10 sec.) 265˚C

**ESD Rating** (Note 4)

- Human-body model 2kV
- Machine model 200V

**Operating Ratings** (Notes 1, 2)

- Input Voltage Range 1.8V to 5.5V
- Junction Temperature \((T\text{J})\) Range \(-40˚C \) to \(+90˚C\)
- Ambient Temperature \((T\text{A})\) Range \(-40˚C \) to \(+85˚C\)

**Thermal Properties**

- Junction-to-Ambient Thermal Resistance \((\theta\text{JA})\), TPA08 Package 220˚C/W

**Electrical Characteristics** (Notes 2, 7)

Limits in standard typeface are for \(T\text{J} = 25˚C\), and limits in **boldface** type apply over the full operating junction temperature range \((-40˚C \leq T\text{J} \leq +90˚C)\). Unless otherwise noted: specifications apply to the LM2780 Typical Application Circuit (pg. 1) with \(\text{V\text{IN}} = 5.0\text{V}, \text{V(SD)} = 0\text{V}, \) and \(C\text{IN} = C\text{OUT} = C\text{1} = C\text{2} = 10\mu\text{F}\). **Note 1:** Absolute Maximum Ratings indicate limits beyond which damage to the component may occur. Operating Ratings are conditions under which operation of the device is guaranteed. Operating Ratings do not imply guaranteed performance limits. For guaranteed performance limits and associated test conditions, see the Electrical Characteristics table.

**Note 2:** All voltages are with respect to the potential at the GND pin.

**Note 3:** \(V\text{OUT}\) may be shorted to GND for one second without damage when the ambient temperature is at or below 85˚C. Prolonged or repeated shorts of \(V\text{OUT}\) to GND may damage the device, and should be avoided.

**Note 4:** The human-body model is a 100pF capacitor discharged through a 1.5kΩ resistor into each pin. The machine model is a 200pF capacitor discharged directly into each pin.

**Note 5:** Maximum ambient temperature \((T\text{A-MAX})\) is dependent on the maximum operating junction temperature \((T\text{J-MAX-OP} = 90˚C)\), the maximum power dissipation of the device in the application \((P\text{D-MAX})\), and the junction-to-ambient thermal resistance of the part in the application \((\theta\text{JA})\), as given by the following equation:

\[
T\text{A-MAX} = T\text{J-MAX-OP} - (\theta\text{JA} x P\text{D-MAX})
\]

**Note 6:** Junction-to-ambient thermal resistance of the micro SMD package is highly application and board-layout dependent.

**Note 7:** Max and Min limits are guaranteed by design, test, or statistical analysis. Typical numbers are not guaranteed, but do represent the most likely norm.

**Note 8:** \(C\text{IN}, C\text{OUT}, C\text{1}, \) and \(C\text{2}: \) Low-ESR Surface-Mount Ceramic Capacitors (MLCCs) used in setting electrical characteristics.

**Note 9:** Output resistance is a model for the voltage drop at the output, resulting from internal switch resistance, capacitor ESR, and charge pump charge transfer characteristics. Output voltage can be predicted with the following equation: 

\[
V\text{OUT} = \left\lbrack V\text{IN} - \left(I\text{OUT} x R\text{OUT}\right)\right\rbrack
\]}
Typical Performance Characteristics

Unless otherwise specified, $T_A = 25^\circ$C, $C_{IN} = C_{OUT} = C1 = C2 = 10\mu$F.

- **Output Voltage vs. Load Current**
- **Power Efficiency vs. Load Current**
- **Output Resistance vs. Temperature ($I_{OUT} = 10mA$)**
- **Supply Current vs. Temperature ($I_{OUT} = 0$)**
- **Switching Frequency vs. Temperature**
- **Output Voltage Ripple vs. Output Current**
Operation Description

The LM2780 is a switched capacitor voltage inverter that produces a negative output voltage from a positive input voltage. To minimize output voltage ripple, the LM2780 contains two charge pump inverters that operate 180° out of phase. These two charge pumps can be seen in the block diagram above.

A basic switched capacitor inverter is a two-phase charge pump circuit that transfers charge from the input to the output using a flying capacitor. Charge Pump 1 in the block diagram will be used to illustrate the operation of a single charge pump. Disregard Charge Pump 2 in the diagram for now. In phase 1 (φ1), the CLK1A signal of Charge Pump 1 is high, and MOSFET switches S1A and S1B are ON. For Charge Pump 1, this is the charge phase, as the flying capacitor C1 is charged to the input voltage. In the second phase (φ2), the positive-charged plate of C1 is connected to GND through switch S1C, and the negative-charged plate is connected to the output through switch S1D. This results in the output voltage being approximately equal in magnitude to the input voltage, but opposite in sign (VOUT ~ = -VIN). In this pump phase, charge stored on the flying capacitor supplies the current to the load and transfers charge to the output capacitor.

This basic inverter has ripple in the output voltage. During the charge phase, the load current is supplied by the charge on the output capacitor. As charge is pulled off COUT, the voltage across the capacitor drops, and the magnitude of the output voltage (|VOUT|) falls. During the pump phase, the flying capacitor transfers charge to the COUT, elevating both the voltage across the COUT and the magnitude of the output voltage.

The LM2780 contains two charge pump inverters running 180° out of phase. Notice in the block diagram that the clock connections on Charge Pump 2 are opposite of the clock connections to Charge Pump 1. Thus, when Charge Pump 1 is in the charge phase, Charge Pump 2 is in the pump phase, and vice-versa. With this double-pump technology, there is always a flying capacitor connected to the output. This results in significantly lower output voltage ripple than that of a single-pump inverter.

OUTPUT VOLTAGE RIPPLE

Several factors influence the magnitude of voltage ripple on the output of the LM2780. Primary influences are output capacitance, flying capacitance, load current, input voltage, and output capacitor ESR.

The magnitude of the output voltage ripple is difficult to predict with equations when the LM2780 is double pumping. Refer to the Typical Performance Characteristic curves for this information. In general, ripple decreases with increased output capacitance, decreased load current, a lower input voltage, a smaller flying capacitance and/or a smaller output capacitor ESR.

When only one charge pump is active (C2 removed), the output ripple is more predictable, and can be estimated with the following equation:

\[ V_{\text{RIPPLE}} = \left( \frac{0.5 \times I_{\text{OUT}}}{f_{\text{SW}} \times C_{\text{OUT}}} \right) + \left( 2 \times I_{\text{OUT}} \times \text{ESR}_{\text{Cout}} \right) \]
Output resistance ($R_{OUT}$) models the internal non-idealities of a charge pump that result in droop in the output voltage. The effect of output resistance on output voltage is expressed in the following equation:

$$V_{OUT} = V_{IN} - (|I_{OUT}| \times R_{OUT})$$

Output resistance is a function of the internal switch resistance ($R_{SW}$), flying capacitance ($C_1$), flying capacitor equivalent series resistance ($ESR_{C1}$), output capacitor ESR ($ESR_{out}$), and internal switching frequency ($f_{SW}$). When the LM2780 operates as a single charge pump ($C_2$ removed), the output resistance can be approximated by the following equation:

1 Fly Cap: $R_{OUT1} \approx 2R_{SW1} + \left(\frac{1}{f_{SW}C_1}\right) + 4ESR_{C1} + ESR_{out}$

$R_{SW1}$ is the sum of the ON resistance of the four internal MOSFET switches of Charge Pump 1.

With both $C_1$ and $C_2$ in place, the double pumping topology of the LM2780 cuts the output resistance in half:

2 Fly Caps: $R_{OUT2} \approx 0.5xR_{OUT1}$

Recommendations for minimizing output resistance include increasing flying capacitance and minimizing output and flying capacitor ESR.

---

**CAPACITOR SELECTION**

Surface-mount multi-layer ceramic capacitors are recommended for use with the LM2780. These capacitors are small, inexpensive and have very low equivalent series resistance ($ESR, < 15\text{m}^\Omega$ typ.). Tantalum capacitors, OS-CON capacitors, and aluminum electrolytic capacitors generally are not recommended for use with the LM2780 due to their high ESR, as compared to ceramic capacitors.

For most applications, ceramic capacitors with $X7R$ or $X5R$ temperature characteristic are preferred for use with the LM2780. These capacitors have tight capacitance tolerance (as good as $\pm 10\%$), hold their value over temperature ($X7R: \pm 15\%$ over $-55^\circ C$ to $125^\circ C$; $X5R: \pm 15\%$ over $-55^\circ C$ to $85^\circ C$), and typically have little voltage coefficient.

Capacitors with $Y5V$ and/or $Z5U$ temperature characteristic are generally not recommended for use with the LM2780. These types of capacitors typically have wide capacitance tolerance ($+80\%, -20\%$), vary significantly over temperature ($Y5V: +22\%, -82\%$ over $-30^\circ C$ to $+85^\circ C$ range; $Z5U: +22\%, -56\%$ over $+10^\circ C$ to $+85^\circ C$ range), and have poor voltage coefficients. Under some conditions, a nominal $1\mu F$ $Y5V$ or $Z5U$ capacitor could have a capacitance of only $0.1\mu F$. Such deviation would severely affect performance of the LM2780 circuit.
LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.

2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
