## STEP-UP, FOR LCD BIAS SUPPLY, 3-CHANNEL SWITCHING REGULATOR

## S-8335 Series

The S-8335 Series is a bias supply IC for a Multi Line Addressing (MLA) driven LCD using a dual-line simultaneous selection mode. This IC supports medium-sized LCD panels. Two step-up type and one inverter type PFM control CMOS switching regulators supply the required positive or negative power to the two MLA-driven LCD common drivers and segment drivers. Because of its CMOS structure, the current consumption of the S-8335 Series is extremely low, which makes it ideal for the LCD power supply of portable equipment that requires low power consumption. Also, an extremely low power consumption LCD module can be created by using the S-8335 Series with the LCD common driver (HD66523R*1: Manufactured by Hitachi, Ltd.) and segment driver (HD66522*1: Manufactured by Hitachi, Ltd.).
*1:These drivers are able to support 1/240duty and 1/200duty.

## Features

- Supports four types of LCD panels (1/240 duty, $1 / 200$ duty, $1 / 160$ duty, and $1 / 120$ duty).
- Input voltage range: 2.4 to 5.0 V (The S-8335 can be driven by a single direct-coupled lithium battery.)
- Output voltage range

Common driver positive power supply (VRH) output voltage range(typ.value)
8.91 to 16.59 V (S-8335A240FT)
8.22 to 15.30 V (S-8335A200FT)
7.48 to 13.93 V (S-8335A160FT)
6.66 to 12.41 V (S-8335A120FT)
(This supply can be varied by on-chip 6-bit electric volume. Power MOSFET is built in.)
Common driver negative power supply (VRL) output voltage range(typ.value)

$$
\begin{aligned}
& -6.87 \text { to }-12.80 \mathrm{~V}(\mathrm{~S}-8335 \mathrm{~A} 240 \mathrm{FT}) \\
& -6.18 \text { to }-11.49 \mathrm{~V}(\mathrm{~S}-8335 \mathrm{~A} 200 \mathrm{FT}) \\
& -5.44 \text { to }-10.13 \mathrm{~V}(\mathrm{~S}-8335 \mathrm{~A} 160 \mathrm{FT}) \\
& -4.61 \text { to }-8.59 \mathrm{~V}(\mathrm{~S}-8335 \mathrm{~A} 120 \mathrm{FT})
\end{aligned}
$$

Segment driver positive power supply (VCH) output voltage range 2.0 to 3.8 V
Segment driver intermediate potential (VM) output voltage range 1.0 to 1.9 V
Icon positive power supply (VICON) output voltage range 1.0 to 2.2 V (This supply can be set arbitrarily by external resistors.)

- Low current consumption
$100 \mu \mathrm{~A}$ typ. (mode $1, \mathrm{~V}_{\mathrm{BAT}}=3 \mathrm{~V}$ )
$10 \mu \mathrm{~A}$ typ. $\left(\operatorname{mode} 2, \mathrm{~V}_{\mathrm{BAT}}=3 \mathrm{~V}\right)$
$1 \mu \mathrm{~A}$ max. (mode $3, \mathrm{~V}_{\mathrm{BAT}}=3 \mathrm{~V}$ )
- Triple operation mode function: Triple mode switching according to 2-bit input

Mode 1: Normal operation
Mode 2: Icon mode (reference voltage circuit- and regulator S-only operation)
Mode 3: Standby mode (power off)

- Power-off function

Stops step-up or step-down operation and short circuits VRH and VRL to VSS by on-chip and external Nch transistors.

- Soft-start function: This function can be set according to an external capacitor (CSS).
- Oscillation frequency: $100 \mathrm{kHz} \pm 20 \mathrm{kHz}$, Duty $=50 \%$
- Lead-free products

## Applications

- Power supply for medium-sized LCD panel

## Package Name

- 24-pin TSSOP package (PKG diagram code: FT024-A)

■ Block Diagram

Figure 1 Block Diagram
Note:
Except for op-amp X, all of the power for the internal circuits of the S-8335 Series is supplied by the VBAT pins. The power supply for op-amp $X$ uses $\mathrm{V}_{\text {оUт3 }}$, which is generated by stepping up $\mathrm{V}_{\text {BAT }}$ using DC/DC $U$. Short-circuit the VOUT3 and VDDX pins as shown in the figure above.

## Selection Guide

1. Product name

$$
\begin{aligned}
& S-8335 A \underline{\underline{X X X}} \underline{\underline{F T}}-T B-G \\
& \begin{array}{l}
\begin{array}{l}
\text { XXX } \\

\\
\\
\end{array} \quad \text { Product type } \quad \text { 240: } 1 / 240 \text { duty support }
\end{array} \\
& \text { 200: 1/200 duty support } \\
& \text { 160: 1/160 duty support } \\
& \text { 120: 1/120 duty support }
\end{aligned}
$$

2. Product list

| S-8335AXXXFT Series | Bias Ratio | Common Driver Positive <br> Power Supply VRH <br> Output Voltage Range [V] |  | Common Driver Negative <br> Power Supply VRL <br> Output Voltage Range [V] |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  | $\mathrm{V}_{\text {RH_min }}$ | $\mathrm{V}_{\text {RH_max }}$ | $\mathrm{V}_{\text {RL_min }}$ | $\mathrm{V}_{\text {RL_max }}$ |
| S-8335A240FT-TB-G | 8.75 | 8.91 | 16.59 | -6.87 | -12.80 |
| S-8335A200FT-TB-G | 8.04 | 8.22 | 15.30 | -6.18 | -11.49 |
| S-8335A160FT-TB-G | 7.33 | 7.48 | 13.93 | -5.44 | -10.13 |
| S-8335A120FT-TB-G | 6.50 | 6.66 | 12.41 | -4.61 | -8.59 |

Note: $\mathrm{V}_{\text {RH_min }}$ and $\mathrm{V}_{\text {RL_min }}$ indicate the typical value of the VRH and VRL output voltage, respectively, when the electric volume is set to the minimum, and $\mathrm{V}_{\mathrm{RH} \text { _max }}$ and $\mathrm{V}_{\mathrm{RL} \text { _max }}$ indicate the typical value of the VRH and VRL output voltage, respectively, when the electric volume is set to the maximum. Also, $\mathrm{V}_{\text {RH_max }}$ is obtained from $\mathrm{V}_{\text {RETGO }} \times 7.136$ and $\mathrm{V}_{\text {RH_min }}$ is obtained from $\mathrm{V}_{\text {RETGO }} \times$ 3.832, where $\mathrm{V}_{\text {RETGO }}$ is the regulator $T$ output voltage.

## Pin Assignment

| Pin No. | Pin Name |  |
| :---: | :--- | :--- |
| 1 | CONT1 | External inductor 1 connection pin |
| 2 | VDIN | Electric volume data input pin |
| 3 | VCLK | Electric volume clock input pin |
| 4 | VSTR_B | Electric volume strobe signal input pin |
| 5 | VSS | GND pin |
| 6 | VOUT1 | Switching regulator P output voltage pin |
| 7 | CSS | Soft start capacitor connection pin |
| 8 | VREGTO | Regulator T output pin |
| 9 | VREGTF | Regulator T feedback input pin |
| 10 | VREGSO | Regulator S output pin |
| 11 | VREGSF | Regulator S feedback input pin |
| 12 | VBAT | Power supply pin |
| 13 | VYO | OP amplifier Y output pin |
| 14 | VQERR | Switching regulator Q output voltage monitoring pin |
| 15 | EXT2 | Switching regulator Q external transistor connection pin |
| 16 | VBAT | Power supply pin |
| 17 | VSS | GND pin |
| 18 | VXO | OP amplifier X output pin |
| 19 | VDDX | OP amplifier X power supply pin |
| 20 | VREFU | Switching regulator U internal reference voltage pin |
| 21 | VOUT3 | Switching regulator U output voltage pin |
| 22 | MC2 | Operating mode control pin 2 |
| 23 | MC1 | Operating mode control pin 1 |
| 24 | CONT3 | External inductor 3 connection pin |
| 2 |  |  |

## Absolute Maximum Ratings

(Unless otherwise specified: $\mathrm{T}_{\mathrm{OPR}}=25^{\circ} \mathrm{C}$ )

| Parameter | Symbol | Ratings | Unit |
| :--- | :--- | :--- | :---: |
| VBAT pin voltage | $\mathrm{V}_{\mathrm{BAT}}$ | 8 | V |
| CONT1 pin voltage | $\mathrm{V}_{\mathrm{CONT} 1}$ | -0.3 to +20 | V |
| CONT1 pin current | $\mathrm{I}_{\mathrm{CONT} 1}$ | 300 | mA |
| VOUT1 pin voltage | $\mathrm{V}_{\mathrm{OUT} 1}$ | -0.3 to +20 | V |
| EXT2 pin voltage | $\mathrm{V}_{\mathrm{EXT} 2}$ | -0.3 to $\mathrm{V}_{\mathrm{BAT}}+20$ | V |
| EXT2 pin current | $\mathrm{I}_{\mathrm{EXT} 2}$ | $\pm 50$ | mA |
| CONT3 pin voltage | $\mathrm{V}_{\text {CONT3 }}$ | -0.3 to +8 | V |
| CONT3 pin current | $\mathrm{I}_{\mathrm{CONT}}$ | 200 | mA |
| VOUT3 pin voltage | $\mathrm{V}_{\mathrm{OUT3}}$ | -0.3 to +8 | V |
| VQERR pin voltage | $\mathrm{V}_{\mathrm{QERR}}$ | -0.3 to +8 | V |
| VDDX pin voltage | $\mathrm{V}_{\mathrm{DDX}}$ | 8 | V |
| VXO pin voltage | $\mathrm{V}_{\mathrm{XO}}$ | -0.3 to $\mathrm{V}_{\mathrm{DDX}}+0.3$ | V |
| Other pin voltage |  | -0.3 to $\mathrm{V}_{\mathrm{BAT}}+0.3$ | V |
| Power dissipation | $\mathrm{P}_{\mathrm{D}}$ | 650 | mW |
| Operating temperature range | $\mathrm{T}_{\mathrm{OPR}}$ | -20 to +70 | ${ }^{\circ} \mathrm{C}$ |
| Storage temperature range | $\mathrm{T}_{\mathrm{STG}}$ | -40 to +125 | ${ }^{\circ} \mathrm{C}$ |

Note: Although this IC incorporates an electrostatic protection circuit, the user is urged to avoid subjecting the circuit to an extremely high static electricity or voltage in excess of its performance.

## ■ Electrical Characteristics

## Note:

The data specifications are based on measured results using recommended peripheral parts
(see $\square$ Recommended Peripheral Parts).

Common
(Unless otherwise specified: $\mathrm{V}_{\mathrm{BAT}}=3.0 \mathrm{~V}, \mathrm{~T}_{\mathrm{OPR}}=25^{\circ} \mathrm{C}$ )

| Item | Symbol | Conditions | Min. | Typ. | Max. | Unit | Measurement Circuit |

Note 1: The regulator $S$ input (reference voltage generation circuit output) voltage has been trimmed to 0.9 V when shipped. Also, the external resistance RS1 and RS2 of the recommended peripheral parts have been set so that $\mathrm{V}_{\text {ICON }}=1.6 \mathrm{~V}$. When a $\mathrm{V}_{\text {Icon }}$ value other than 1.6 V is used, select the resistance RS1 and RS2 values to match the $\mathrm{V}_{\text {ICoN }}$ voltage used. Also change the RT1 and RT2 values at the same time, because the RT1 and RT2 values are selected based on $\mathrm{V}_{\text {ICON }}=1.6 \mathrm{~V}$.
Note 2: CRS1 is not usually necessary. Add the capacitance only when regulator $S$ is oscillating. Evaluate the actual device using capacitance value on the order of $0.1 \mu \mathrm{~F}$.
Note 3: The output voltage precision does not include external resistance dispersion.

■ Measurement Circuits

Figure 3 Measurement Circuits

## ■ Operation

The S-8335 Series has two step-up type and one inverter type CMOS on-chip switching regulators. These switching regulators employ the pulse frequency modulation (PFM) method to provide low current consumption features.

## 1. Operation Overview

The output of the reference voltage generation circuit is the input to regulator S . The output of regulator $S$ is the input to regulator $T$. After the extremely steep rise has been blunted by an RC low-pass filter, the output of regulator $T$ becomes the DC/DC $P$ reference voltage. The DC/DC $P$ output (pin name: VOUT1) that is controlled by the electric volume is obtained based on this reference voltage. The DC/DC P output becomes the common driver positive power supply (VRH).

VRH is divided by internal resistors and becomes the input of OP amplifier $X$. The output (pin name: VXO) of OP amplifier $X$ becomes the segment driver positive power supply (VCH).

Also, the input voltage of OP amplifier X becomes the reference voltage of the DC/DC U error amplifier. The DC/DC U output (pin name: VOUT3) is obtained so that it becomes 1.05 times larger than this reference voltage. The DC/DC $U$ output voltage can be used for the OP amplifier $X$ power supply voltage.

VCH is divided by internal resistors and becomes the input of OP amplifier Y. The output (pin name: VYO ) of OP amplifier Y becomes the segment driver intermediate potential (VM).

VM becomes the reference voltage of the DC/DC Q error amplifier. DC/DC Q oscillates and VRL is obtained so that the common driver negative power supply (VRL) and VRH are symmetric around VM.
2. Step-up type switching regulators (DC/DC P and DC/DC U)

*: In DC/DC P, R1 is a variable resistance controlled by the electric volume.

Figure 4 DC/DC P and DC/DC U

The fundamental equations $\{(1)$ to (7) \} of the step-up type regulators are shown below (see Figure 4). CONT pin voltage $\left(\mathrm{V}_{\mathrm{A}}\right)$ immediately after M 1 is turned on ( $\mathrm{I}_{\mathrm{L}}$, which is the current that flows to L , is zero):

$$
\begin{equation*}
\mathrm{V}_{\mathrm{A}}=\mathrm{V}_{\mathrm{s}} \tag{1}
\end{equation*}
$$

( $\mathrm{V}_{\mathrm{S}}$ : Unsaturated voltage of M 1 )

Change in $L_{L}$ with time:

$$
\begin{equation*}
\frac{\mathrm{d} \mathrm{IL}_{\mathrm{L}}}{\mathrm{dt}}=\frac{\mathrm{V}_{\mathrm{L}}}{\mathrm{~L}}=\frac{\mathrm{V}_{\mathrm{IN}}-\mathrm{VS}_{\mathrm{S}}}{\mathrm{~L}} \tag{2}
\end{equation*}
$$

Result of integrating the above equation $\left(\mathrm{I}_{\mathrm{L}}\right)$ :

$$
\begin{equation*}
\mathrm{IL}_{\mathrm{L}}=\left(\frac{\mathrm{VIN}-\mathrm{Vs}}{\mathrm{~L}}\right) \cdot \mathrm{t} \tag{3}
\end{equation*}
$$

The current $\mathrm{I}_{\mathrm{L}}$ flows during time $\mathrm{t}_{\mathrm{ON}}$. This time $\left(\mathrm{t}_{\mathrm{ON}}\right)$ is determined according to the oscillation frequency of OSC.
Peak current ( $\mathrm{l}_{\mathrm{PK}}$ ) after $\mathrm{t}_{\mathrm{ON}}$ :

$$
\begin{equation*}
\mathrm{I}_{\mathrm{PK}}=\left(\frac{\mathrm{V}_{\mathrm{IN}}-\mathrm{Vs}_{\mathrm{s}}}{\mathrm{~L}}\right) \cdot \operatorname{toN} \tag{4}
\end{equation*}
$$

The energy stored in $L$ at this time is represented by $1 / 2 \cdot L\left(l_{\mathrm{PK}}\right)^{2}$.
Next, when M1 is turned off ( $t_{\text {OFF }}$ ), the energy stored in $L$ is emitted through a diode, and a counter voltage $\left(\mathrm{V}_{\mathrm{L}}\right)$ is generated.
$V_{\mathrm{L}}$ :

$$
\begin{equation*}
\mathrm{V}_{\mathrm{L}}=\left(\mathrm{Vout}^{2}+\mathrm{V}_{\mathrm{D}}\right)-\mathrm{V}_{\mathrm{IN}} \tag{5}
\end{equation*}
$$

$$
\left(\mathrm{V}_{\mathrm{D}}: \text { Diode forward voltage }\right)
$$

The CONT pin voltage rises by the voltage corresponding to $\mathrm{V}_{\text {OUT }}+\mathrm{V}_{\mathrm{D}}$.
Change with time of current $\left(\mathrm{I}_{\mathrm{L}}\right)$ that flows to $\mathrm{V}_{\text {OUT }}$ through a diode during time $\mathrm{t}_{\mathrm{OFF}}$ :

$$
\begin{equation*}
\frac{\mathrm{dIL}}{\mathrm{dt}}=\frac{\mathrm{V}_{\mathrm{L}}}{\mathrm{~L}}=\frac{\mathrm{Vout}_{\mathrm{V}}+\mathrm{V}_{\mathrm{D}}-\mathrm{V}_{\mathrm{IN}}}{\mathrm{~L}} \tag{6}
\end{equation*}
$$

Result of integrating the above equation:

$$
\begin{equation*}
\mathrm{I}_{\mathrm{L}}=\mathrm{IPK}-\left(\frac{\mathrm{Vout}+\mathrm{V}_{\mathrm{D}}-\mathrm{V}_{\mathrm{IN}}}{\mathrm{~L}}\right) \cdot \mathrm{t} \tag{7}
\end{equation*}
$$

During $t_{\text {ON }}$, the energy is stored in $L$ and not transmitted to $V_{\text {OUT }}$. When output current (lout) flows from $V_{\text {OUt }}$, the capacitor ( $\mathrm{C}_{\text {OUT }}$ ) energy is used. As a result, the $\mathrm{C}_{\text {OUt }}$ pin voltage decreases and reaches its lowest value after time ton. When M1 is turned off, the energy stored in $L$ is transmitted through the diode to $\mathrm{C}_{\text {Out }}$, and the $\mathrm{C}_{\text {OUt }}$ pin voltage rises dramatically. $\mathrm{V}_{\text {OUt }}$ is a time function that indicates the maximum value (ripple voltage: $\mathrm{V}_{\mathrm{P}-\mathrm{P}}$ ) when the current flowing through the diode to $\mathrm{V}_{\text {Out }}$ matches the load current lout.

This ripple voltage value is calculated below.
$l_{\text {OUT }}$ when the time from immediately after $t_{\text {ON }}$ until $\mathrm{V}_{\text {OUT }}$ reaches its highest level is set to $\mathrm{t}_{1}$ :

$$
\begin{align*}
& \text { Iout }=\operatorname{IPK}-\left(\frac{\text { Vout }+\mathrm{V}_{\mathrm{D}}-\mathrm{V}_{\text {IN }}}{\mathrm{L}}\right) \cdot \mathrm{t}_{1}  \tag{8}\\
& \therefore \mathrm{t}_{1}=(\mathrm{I} \text { If }-\mathrm{Iout}) \cdot\left(\frac{\mathrm{L}}{\mathrm{VOUT}^{2}+\mathrm{V}_{\mathrm{D}}-\mathrm{V}_{\text {IN }}}\right) \tag{9}
\end{align*}
$$

Since $\mathrm{I}_{\mathrm{L}}=0$ at time $\mathrm{t}_{\text {OFF }}$ (when all inductor energy was emitted), the following is obtained from equation (7):

$$
\begin{equation*}
\frac{L}{V_{\text {OUT }}+\text { VD }- \text { VIN }}=\frac{\text { tofF }}{\text { IPK }} \tag{10}
\end{equation*}
$$

The following is obtained by substituting equation (10) into equation (9):

$$
\begin{equation*}
\mathrm{t}_{1}=\mathrm{toFF}-\left(\frac{\text { Iout }}{\text { IPK }}\right) \cdot \mathrm{t}_{\mathrm{OFF}} \tag{11}
\end{equation*}
$$

The amount of electric charge $\Delta Q_{1}$ charged in $C_{\text {OUT }}$ during time $t_{1}$ :

$$
\begin{align*}
& \Delta \mathrm{Q}_{1}=\int_{0}^{\mathrm{t} 1} \mathrm{LL} d \mathrm{t}=\mathrm{I} \text { PK } \cdot \int_{0}^{\mathrm{t} 1} \mathrm{dt}-\frac{\text { Vout }+\mathrm{V}_{\mathrm{D}}-\mathrm{V}_{\text {IN }}}{\mathrm{L}} \cdot \int_{0}^{\mathrm{t} 1} \mathrm{t} d \mathrm{t} \\
& =\mathrm{IPK} \bullet \mathrm{t}_{1}-\frac{\text { Vout }+\mathrm{V}_{\mathrm{D}}-\mathrm{V}_{\text {IN }}}{\mathrm{L}} \cdot \frac{1}{2} \mathrm{t}_{1}{ }^{2} \tag{12}
\end{align*}
$$

The following is obtained by substituting equation (9) into equation (12)

$$
\begin{equation*}
\Delta \mathrm{Q}_{1}=\left[\operatorname{IPK}-\frac{1}{2}(\mathrm{I} \text { IPK }-\mathrm{IOUT})\right] \cdot \mathrm{t}_{1}=\left(\frac{\mathrm{IPK}+\text { Iout }}{2}\right) \cdot \mathrm{t}_{1} \tag{13}
\end{equation*}
$$

The voltage rise $\left(V_{P-P}\right)$ due to $\Delta Q_{1}$ is as follows:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{P}-\mathrm{P}}=\frac{\Delta \mathrm{Q}_{1}}{\text { Cout }}=\frac{1}{\text { Cout }} \cdot\left(\frac{\mathrm{IPK}+\text { Iout }}{2}\right) \cdot \mathrm{t}_{1} \tag{14}
\end{equation*}
$$

The following is obtained when the $l_{\text {Out }}$ consumed during time $t_{1}$ and $R_{\text {ESR }}$, which is the Electric Series Resistance (ESR) of Cout, are taken into consideration:

$$
\begin{equation*}
\mathrm{V}_{\text {P-P }}=\frac{\Delta \mathrm{Q}_{1}}{\text { Cout }}=\frac{1}{\text { Cout }} \cdot\left(\frac{\text { IPK }+ \text { Iout }}{2}\right) \cdot \mathrm{t}_{1}+\left(\frac{\text { IPK }+ \text { Iout }}{2}\right) \cdot \operatorname{RESR}-\frac{\text { Iout } \cdot \mathrm{t}_{1}}{\text { Cout }} \tag{15}
\end{equation*}
$$

The following is obtained when equation (11) is substituted into equation (15):

$$
\begin{equation*}
\mathrm{V}_{\mathrm{P}-\mathrm{P}}=\frac{(\mathrm{IPK}-\mathrm{Iout})^{2}}{2 \text { IPK }} \cdot \frac{\mathrm{tofF}}{\mathrm{CouT}}+\left(\frac{\mathrm{IPK}+\mathrm{IouT}}{2}\right) \cdot \mathrm{ReSR}^{2} \tag{16}
\end{equation*}
$$

Effective ways to reduce the ripple voltage are to increase the capacitance of the capacitor connected to the output pin and to reduce its ESR.

## Note:

Although this IC has an on-chip soft-start circuit, a rush current flows because the output capacitor (Cout) and load capacitance component are charged up via the coil and diode on power application. Therefore, care must be taken.
3. Inverter type switching regulator (DC/DC Q)

The fundamental equations of the inverter type regulator are shown below.
Point A voltage immediately after $M 1$ is turned on ( $I_{L}$, which is the current that flows to $L$, is zero):

$$
\begin{equation*}
\mathrm{V}_{\mathrm{A}}=\mathrm{V}_{\mathrm{IN}}-\mathrm{V}_{\mathrm{S}} \tag{17}
\end{equation*}
$$

$\left(\mathrm{V}_{\mathrm{S}}\right.$ : Unsaturated voltage of M 1$)$

Change in $I_{L}$ with time:

$$
\begin{equation*}
\frac{\mathrm{d} \mathrm{IL}_{\mathrm{L}}}{\mathrm{dt}}=\frac{\mathrm{V}_{\mathrm{L}}}{\mathrm{~L}}=\frac{\mathrm{V}_{\mathrm{IN}}-\mathrm{Vs}_{\mathrm{s}}}{\mathrm{~L}} \tag{18}
\end{equation*}
$$

Figure 5 Inverter Type Switching Regulator

Result of integrating the above equation ( $I_{\mathrm{L}}$ ):

$$
\begin{equation*}
\mathrm{IL}_{\mathrm{L}}=\left(\frac{\mathrm{V}_{\mathrm{IN}}-\mathrm{Vs}}{\mathrm{~L}}\right) \cdot \mathrm{t} \tag{19}
\end{equation*}
$$

The current $\mathrm{I}_{\mathrm{L}}$ flows during time $\mathrm{t}_{\mathrm{ON}}$. This time $\left(\mathrm{t}_{\mathrm{ON}}\right)$ is determined according to the oscillation frequency of OSC.

Peak current ( $\mathrm{l}_{\mathrm{PK}}$ ) after $\mathrm{t}_{\mathrm{ON}}$ :

$$
\begin{equation*}
\mathrm{IPK}=\left(\frac{\mathrm{V}_{\mathrm{IN}}-\mathrm{Vs}_{\mathrm{s}}}{\mathrm{~L}}\right) \cdot \operatorname{toN} \tag{20}
\end{equation*}
$$

The energy stored in $L$ at this time is represented by $1 / 2 \cdot L\left(l_{\mathrm{PK}}\right)^{2}$.
Next, when M1 is turned off, the energy stored in $L$ is emitted through ground $\rightarrow$ capacitor $\rightarrow$ diode ( Di ), and a counter voltage $\left(\mathrm{V}_{\mathrm{L}}\right)$ is generated at the same time.
$V_{L}$ :

$$
\begin{equation*}
\mathrm{V}_{\mathrm{L}}=-\left(\text { Vout }+\mathrm{V}_{\mathrm{D}}\right) \tag{21}
\end{equation*}
$$

$\left(\mathrm{V}_{\mathrm{D}}\right.$ : Diode forward voltage)

Change with time of current $\left(I_{L}\right)$ that flows to $-V_{\text {OUT }}$ through a capacitor during time $t_{\text {OFF }}$ :

$$
\begin{equation*}
\frac{\mathrm{d} \mathrm{IL}_{\mathrm{L}}}{\mathrm{dt}}=\frac{\mathrm{V}_{\mathrm{L}}}{\mathrm{~L}}=\frac{\mathrm{VouT}+\mathrm{V}_{\mathrm{D}}}{\mathrm{~L}} \tag{22}
\end{equation*}
$$

Result of integrating the above equation:

$$
\begin{equation*}
\mathrm{I}_{\mathrm{L}}=\mathrm{IPK}-\left(\frac{\mathrm{VouT}+\mathrm{VD}}{\mathrm{~L}}\right) \cdot \mathrm{t} \tag{23}
\end{equation*}
$$

During $t_{\text {ON }}$, the energy is stored in $L$ and not transmitted to $-V_{\text {OUt }}$. When output current (lout) flows from - $\mathrm{V}_{\text {out, }}$ the capacitor ( $\mathrm{C}_{\text {out }}$ ) energy is used. As a result, the $\mathrm{C}_{\text {out }}$ pin voltage decreases and reaches its lowest value after time $\mathrm{t}_{\mathrm{ON}}$. When M1 is turned off, the energy stored in L is transmitted through the diode to $\mathrm{C}_{\text {Out }}$, and the $\mathrm{C}_{\text {Out }}$ pin voltage rises dramatically. $\mathrm{V}_{\text {OUt }}$ is a time function that indicates the maximum value (ripple voltage: $\mathrm{V}_{\mathrm{P}-\mathrm{P}}$ ) when the current flowing through the diode to $\mathrm{V}_{\text {OUt }}$ matches the load current lout.

This ripple voltage value is calculated below.
$l_{\text {OUT }}$ when the time from immediately after $t_{\text {ON }}$ until $V_{\text {OUT }}$ reaches its highest level is set to $t_{1}$ :

$$
\begin{align*}
& \text { Iout }=\operatorname{IPK}-\left(\frac{\text { Vout }+V_{D}}{L}\right) \cdot \mathrm{t}_{1} \ldots \ldots  \tag{24}\\
& \therefore \mathrm{t}_{1}=(\mathrm{I} \text { IPK }- \text { Iout }) \cdot\left(\frac{\mathrm{L}}{\text { Vout }+\mathrm{V}_{\mathrm{D}}}\right) . \tag{25}
\end{align*}
$$

Since $\mathrm{I}_{\mathrm{L}}=0$ at time $\mathrm{t}_{\mathrm{OFF}}$ (when all inductor energy was emitted), the following is obtained from equation (23):

$$
\begin{equation*}
\frac{\mathrm{L}}{\mathrm{VouT}+\mathrm{VD}_{\mathrm{D}}}=\frac{\text { toff }}{\mathrm{IPK}} \tag{26}
\end{equation*}
$$

The following is obtained by substituting equation (26) into equation (25):

$$
\begin{equation*}
\mathrm{t}_{1}=\mathrm{toFF}-\left(\frac{\mathrm{Iout}}{\mathrm{IPK}}\right) \cdot \mathrm{t}_{\mathrm{oFF}} \tag{27}
\end{equation*}
$$

The amount of electric charge $\Delta Q_{1}$ charged in $C_{\text {OUT }}$ during time $t_{1}$ :

$$
\begin{align*}
& \Delta \mathrm{Q}_{1}=\int_{0}^{\mathrm{t} 1} \text { Iout } \mathrm{dt}=\mathrm{I} \text { IFK } \cdot \int_{0}^{\mathrm{t} 1} \mathrm{dt}-\frac{\text { Vout }+\mathrm{VD}}{\mathrm{~L}} \cdot \int_{0}^{\mathrm{t} 1} \mathrm{tdt} \\
& =\operatorname{IPK} \bullet \mathrm{t}_{1}-\frac{\text { Vout }+\mathrm{VD}}{\mathrm{~L}} \cdot \frac{1}{2} \mathrm{t}^{2}{ }^{2} \tag{28}
\end{align*}
$$

The following is obtained by substituting equation (25) into equation (28)

$$
\begin{equation*}
\Delta \mathrm{Q}_{1}=\operatorname{IPK}-\frac{1}{2}(\mathrm{IPK}-\text { IouT }) \cdot \mathrm{t}_{1}=\frac{\text { IPK }+ \text { IouT }}{2} \cdot \mathrm{t}_{1} \tag{29}
\end{equation*}
$$

The voltage rise $\left(\mathrm{V}_{\mathrm{P}-\mathrm{P}}\right)$ due to $\Delta \mathrm{Q}_{1}$ is as follows:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{P}-\mathrm{P}}=\frac{\Delta \mathrm{Q}_{1}}{\text { Cout }}=\frac{1}{\text { Cout }} \cdot\left(\frac{\text { IPK }+ \text { Iout }}{2}\right) \cdot \mathrm{t}_{1} \tag{30}
\end{equation*}
$$

The following is obtained when the $\mathrm{l}_{\text {OUT }}$ consumed during time $\mathrm{t}_{1}$ is taken into consideration:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{P}-\mathrm{P}}=\frac{\Delta \mathrm{Q}_{1}}{\text { Cout }}=\frac{1}{\text { Cout }} \cdot\left(\frac{\mathrm{IfK}+\text { Iout }}{2}\right) \cdot \mathrm{t}_{1}-\frac{\text { Iout } \cdot \mathrm{t}_{1}}{\text { Cout }} \tag{31}
\end{equation*}
$$

The following is obtained when equation (27) is substituted into equation (31):

$$
\begin{equation*}
\mathrm{V}_{\mathrm{P}-\mathrm{P}}=\frac{(\mathrm{IPK}-\text { Iout })^{2}}{2 \text { IPK }} \cdot \frac{\text { tofF }}{\text { Cout }} \tag{32}
\end{equation*}
$$

## Operation Modes and Mode Control

The mode is switched among modes 1 to 3 according to the 2-bit input from the MC1 and MC2 pins and the MC3 signal. The MC3 signal is not an input to a pin of this IC. It is a signal required for external part control. This signal should be supplied from the LCD driver or LCD controller.
Since the MC1 and MC2 pins are not pulled up or pulled down internally, they should not be in a floating state. Also, note that the current consumption in standby mode may exceed $1 \mu \mathrm{~A}$ if there is a potential difference between the supply voltage of MC1 and MC2 and the supply voltage of the S-8335 Series IC.

| MC1 | MC2 | MC3* $^{*}$ | Operation Mode |
| :---: | :---: | :---: | :--- |
| L | L | H | Mode 1 (Normal operation) |
| L | H | L | Mode 2 (Icon mode) |
| H | X | L | Mode 3 (Standby mode) |

Remark: L: Low level, H: High level, X: Don't care

* MC3 is a signal that is the input to an external switch to forcibly discharge a capacitor in modes 2 and 3.

1. Normal operation mode (MC1=L, MC2=L, MC3=H)

Step-up operation is performed.
2. Icon mode ( $M C 1=L, M C 2=H, M C 3=L)$

Only the reference voltage circuit and regulator $S$ operate. The regulator $S$ output $\mathrm{V}_{\text {REGSo }}$ can be set arbitrarily in the range from 1.0 to 2.2 V by using external resistors RS 1 and RS2. $\mathrm{V}_{\text {REGso }}$ can be used as the icon voltage. Use an RS1 value that matches the temperature characteristics of the panel by combining a series or parallel resistor with a thermistor as necessary. See the section on regulator $S$ for information about the output voltage characteristics of regulator $S$ when the output current is drawn.
3. Standby mode (MC1=H, MC3=L)

The operation of internal circuits is shut down. The current consumption does not exceed $1 \mu \mathrm{~A}$.
When the MC1 pin is set high ("H" level), the operation of all internal circuits stops, and the current consumption is dramatically reduced. At the same time, the VOUT1, VXO, VYO, VREGSO, and VREGTO pins are each short-circuited to $\mathrm{V}_{S S}$ by on-chip Nch transistors. (However, data that was written to the register of the electric volume part is retained if a voltage of at least 2 V is applied between the VBAT and VSS pins.) Since current flows at this time from the VOUT1 pin to $\mathrm{V}_{\mathrm{SS}}$ through a coil and a diode at the input side, a switch for shutting down the current is required.

Figure 6 shows a sample circuit that uses NEC's 2SJ356 (Pch MOSFET) as the current breaker switch. In this sample circuit, the small signal transistor E (Nch MOSFET) is used to turn 2SJ356 on or off by inputting the control signal MC3 to the gate of transistor E.
An invalid current flowing to resistor RA1 during a step-up operation may affect efficiency. Resistor RA1 should be set to a high resistance value to reduce current. However, if the RA1 resistance value is set too high, a voltage drop across resistor RA1 will occur due to the off-leak current of the small signal transistor E, and the 2SJ356 current breaker switch may not turn off. Therefore, care must be taken.

Note:
The efficiency characteristics shown in the reference data, which were measured without a current breaker switch, differ from the efficiency of this sample circuit.

Figure 6 Sample Circuit in Which 2SJ356 is Used

When mode 3 (standby mode) is canceled, the mode returns to the one that was in effect before switching to standby mode. For example, if the IC entered mode 3 from mode 1 , it will return to mode 1 when mode 3 is canceled.

Note 1:
If there is a potential difference between the applied voltage to MC1 and MC2 and the power supply voltage of the S8335 Series, the current consumption in standby mode may exceed $1 \mu \mathrm{~A}$.

For example, when the applied voltage to MC1 and MC2 is 3.0 V and the power supply voltage of the $\mathrm{S}-8335$ Series is 5.0 V, the current consumption in standby mode rises to approximately $2.5 \mu \mathrm{~A}$ at $25^{\circ} \mathrm{C}$ (typ.) (see Figure 7). The reason this occurs is that a penetrating current flows in CMOS logic circuits because the potential of input signals MC1 and MC2 $(3.0 \mathrm{~V})$ is lower than the internal logic power supply voltage $(5.0 \mathrm{~V})$.

Therefore, use this IC in such a way that no potential difference occurs between the applied voltage to MC1 and MC2 and the power supply voltage of the S-8335 Series.

Figure 7 Standby Mode Current Characteristics

Figure 8 Mode Switching

## ■ Electric volume

Figure 9 Block Diagram and Clock Timing of Electric Volume Part

VDIN: This is the data input pin to the electric volume.
"Data 1 " is an input for the " H " level, and "data 0 " is an input for the " L " level. (A high impedance state is prohibited.) When no data is sent, keep VDIN at the "L" level.
VCLK: This is the clock input pin to the electric volume.
The data of the VDIN pin is fetched to the shift register at the clock rising edge. When a clock with more than six bits data is input, the data that had been read is sequentially shifted at each clock pulse, and the last six bits of data become effective.
VSTR_B: This is the strobe signal input pin. When the strobe signal goes low (set to "L" level), the shift register contents are fetched to the latch. The data that is fetched to the latch is sent directly to the electric volume, and consequently the output voltage changes. When the strobe signal goes high (set to "H" level), the latch data is held.

Figure 10 Linearity Error

The electric volume has 6 -bit resolution. The integral and differential linearity errors are $\pm 0.5 \mathrm{LSB}$. For example, if you want the VRH output voltage range to vary between 8.91 and 16.59 V , you can obtain a linearity precision of $\pm 61 \mathrm{mV}$ by selecting the S-8335A240FT.

Since the register contents are undefined when the power is turned on, they must be reset. Even if the MC1 pin or MC2 pin is set high ("H" level) and the MC3 signal is set low ("L" level) and the step-up operation stops, the electric volume register contents are retained if a voltage of at least 2 V is applied between the VBAT and VSS pins. Register "WRITE" and "RESET" operations are also available in this state.

The register is initialized to "000000" and the output voltage is set to its minimum value by setting VCLK = "H" and VSTR_B = "L".

Turn on the power with $\mathrm{MCI}=$ " H " and $\mathrm{MC} 3=$ " L ". Then initialize the register contents by setting VCLK = "H" and VSTR_B="L" and begin the step-up operation by switching the MC1 and MC2 pins low ("L" level) and the MC3 signal high ("H" level).

Caution:
If a step-up operation is started without initializing the data in the register after turning on the power, the maximum output voltage may appear at the VOUT pins and connected devices or instruments may be damaged. It is recommended to connect a pull-down resistor between $\mathrm{V}_{\mathrm{SS}}$ and the external part pins that the MC3 signal enters and to connect a pull-up resistor between the MC1 pin and $V_{\text {BAT }}$.

Note:
If there is a potential difference between the applied voltage to VDIN, VCLK, and VSTR_B and the power supply voltage of the S-8335 Series, the current consumption in standby mode may exceed $1 \mu \mathrm{~A}$. For example, when the applied voltage to VDIN, VCLK, and VSTR_B is 3.0 V and the power supply voltage of the S-8335 Series is 5.0 V , the current consumption in standby mode rises to approximately $2.5 \mu \mathrm{~A}$ at $25^{\circ} \mathrm{C}$ (typ.) (see Figure 11). The reason this occurs is that a penetrating current flows in the CMOS logic circuits because the potential of input signals VDIN, VCLK, and VSTR_B (3.0 V) is lower than the internal logic power supply voltage ( 5.0 V ). A similar situation occurs for the power supply voltage of MC1 and MC2 (see Note in the Mode Control section).

Figure 11 Standby Mode Current Characteristics

## - OP amplifier $X$

The power supply voltage of $O P$ amplifier $X$ is generated using DC/DC $U$ so that it is approximately 1.05 times larger than the output voltage of OP amplifier X. Since the difference between the power supply voltage and output voltage is kept small, the power loss is extremely small and efficiency is increased. Figure 12 shows the output voltage of OP amplifier X when source current is drawn.

Figure 12 OP Amplifier X Output Voltage

## ■ OP amplifier Y

$V_{\text {BAT }}$ is used for the power supply voltage of OP amplifier $Y$. Figures 13 and 14 show the output voltage of OP amplifier Y when source current and sink current are drawn, respectively.

Figure 13 VYO Pin Source Current Characteristics

Figure 14 VYO Pin Sink Current Characteristics

## ■ Regulator S Part

$V_{\text {BAT }}$ is used for the power supply voltage of the regulator $S$ part. The regulator $S$ output $V_{\text {REGSo }}$ can be set arbitrarily in the range from 1.0 to 2.2 V by using external resistor RS1 and RS2. V REGSo can be used as the icon voltage. Use an RS1 value that matches the temperature characteristics of the panel by combining a series or parallel resistor with a thermistor as necessary.
Also, CRS1 is a capacitor for preventing oscillation. It is required only when the regulator oscillates. Adjust the CRS1 value when the RS1 and RS2 values are changed. Using the actual device, confirm that the regulator does not oscillate. Figure 15 shows the voltage $\mathrm{V}_{\text {REGSO }}$ when current is drawn.

Figure $15 \mathrm{~V}_{\text {Regso }}$ Characteristics

## ■ Regulator T Part

$V_{\text {BAT }}$ is used for the power supply voltage of the regulator T part. The regulator T output $\mathrm{V}_{\text {REGTo }}$ can be set by using external resistance RT1 and RT2. Set $\mathrm{V}_{\text {REGTo }}$ to match the voltage range that is to be used.

The common-driver voltage $\mathrm{V}_{\mathrm{RH} \text { _max }}$ is obtained by $\mathrm{V}_{\text {REGTO }} \times 7.136$, and $\mathrm{V}_{\text {RH_min }}$ is obtained by $\mathrm{V}_{\text {REGTO }} \times$ 3.832. Figure 16 shows the voltage $V_{\text {REGTO }}$ when current is drawn.

Figure $16 \mathrm{~V}_{\text {REGto }}$ Characteristics

## ■ Power Supply Rising Edge Sequence

The power supply rising edge sequence is $\mathrm{V}_{\mathrm{RH}}, \mathrm{V}_{\mathrm{CH}}, \mathrm{V}_{\mathrm{M}}, \mathrm{V}_{\mathrm{RL}}$. The falling edge sequence is $\mathrm{V}_{\mathrm{RL}}, \mathrm{V}_{\mathrm{M}}, \mathrm{V}_{\mathrm{CH}}$, $\mathrm{V}_{\mathrm{RH}}$. (See Figure 17.)

Figure 17 Rising and Falling Edge Sequences

## ■ Soft Start

The soft-start function blunts the rising edge of the reference voltage $\mathrm{V}_{\text {REGTO }}$ by using an external capacitor $\mathrm{C}_{\mathrm{Ss}}$ and an internal resistor so that the rush current can be reduced to some degree corresponding to this moderated ascent. However, note that this is not a complete soft start because the switching regulators of the S-8335 Series use PFM control.

## Selection of External Parts

1. Inductor

The inductance value significantly affects the maximum output current $l_{\text {Out }}$ and efficiency $\eta$ (EFFI). Figure 18 shows graphs of the dependency of lout and EFFI for the S-8335 Series on the inductance value L .

$D C-D C P\left(\right.$ Vout $\left.=16.6 \mathrm{~V}, \mathrm{~V}_{\text {bAt }}=3.0 \mathrm{~V}\right)$

DC-DC U (Vout $=3.99 \mathrm{~V}$, Vbat $=3.0 \mathrm{~V}$ )

Figure 18 Dependency of $\mathrm{I}_{\text {OUT }}$ and EFFI on Inductance Value L

As the $L$ value decreases, the peak current $I_{P K}$ increases, and $l_{O U T}$ reaches its maximum at a certain $L$ value. If the $L$ value decreases further, the current driving capability of the switching transistor becomes insufficient, and $\mathrm{l}_{\text {Out }}$ is reduced.

Also, as the $L$ value increases, the power loss due to $I_{P K}$ at the switching transistor decreases, and the efficiency reaches its maximum at a certain $L$ value. If the $L$ value increases further, the power loss due to the series resistance of the coil increases, and efficiency is reduced.
The recommended inductance value is 100 to $150 \mu \mathrm{H}$ for $\mathrm{DC} / \mathrm{DC} P$ and 100 to $180 \mu \mathrm{H}$ for DC/DC Q and DC/DC U.

When you select inductors, pay attention to the permissible current of the inductors. If a current that exceeds the permissible current flows in the inductor, magnetic saturation will occur in the inductor. This may cause a significant decrease in efficiency and may damage the IC due to excessive current.

Therefore, select inductors so that the peak current $I_{P K}$ does not exceed the permissible current. The peak current $I_{P K}$ in non-continuous mode is given by the following equation.

IPK $=\sqrt{\frac{2 \mathrm{Iout} \bullet\left(\mathrm{Vout}+\mathrm{VD}_{\mathrm{D}}-\mathrm{VIN}\right)}{\text { fosc } \bullet \mathrm{L}}} \quad$ (A)
where $\mathrm{f}_{\text {osc }}$ is the oscillation frequency. $\mathrm{V}_{\mathrm{D}}$ is approximately 0.4 V .
For example, assume that output voltage $\mathrm{V}_{\text {OUT }}=16.6 \mathrm{~V}$, with load current $\mathrm{I}_{\text {OUT }}=2 \mathrm{~mA}$, using S-8335A240FT with the input voltage $\mathrm{V}_{\mathrm{IN}}=3 \mathrm{~V}$ and $\mathrm{f}_{\mathrm{osc}}=100 \mathrm{kHz}$. If $150 \mu \mathrm{H}$ is selected for the L value, then $\mathrm{I}_{\mathrm{PK}}=61 \mathrm{~mA}$ from equation (33). Therefore, an inductor having a permissible current of at least 61 mA at an L value of $150 \mu \mathrm{H}$ should be selected.
2. Diode

An off-chip diode must satisfy the following conditions.

- Low forward voltage: $\quad \mathrm{V}_{\mathrm{F}}<0.3 \mathrm{~V}$
- Fast switching speed: 500 ns max.
- Reverse breakdown voltage: $\mathrm{V}_{\text {OUT }}+\mathrm{V}_{\mathrm{F}}$ or more
- Rated current: $\mathrm{I}_{\mathrm{PK}}$ or more

3. Capacitors (CVBAT, CL)

The input capacitor (CVBAT) can improve efficiency by decreasing the power supply impedance and stabilizing the input current. Select the capacitor value according to the impedance of the power supply used. Connect a capacitor of at least $1 \mu \mathrm{~F}$ to each of the two power supply pins.
For the output capacitor (CL), use a capacitor having a small Electric Series Resistance (ESR) and large capacitance to stabilize the ripple voltage. Standard capacitor values are at least $2.2 \mu \mathrm{~F}$ for CL1 and CL2 and at least $10 \mu \mathrm{~F}$ for CL3. In particular, a tantalum electrolytic capacitor having excellent low temperature characteristics and low leakage current characteristics should be used. A capacitor having a large capacitance produces more stable output and leads to higher efficiency.

- Standard Circuits

: small current VSS, $\frac{1}{\pi /}$ : large current VSS

Figure 19 Standard Circuits
Except for op-amp X, all of the power for the internal circuits of the S-8335 Series is supplied by the VBAT pin.

## - Pattern Diagram

In general, the switching regulator is significantly affected by the circuit board wiring. The following figure shows a sample pattern diagram for which the effect of the circuit board wiring is small.

Figure 20 Pattern Diagram
Note the following points when creating a pattern diagram.

- There are two VSS lines (connected inside the IC).
a) VSS (pin No. 5): Large current GND
b) VSS (pin No. 17): Small current (analog) + middle current GND
- Arrange the VSS line and capacitors first. CVBAT, CL1, CL2, and CL3 are particularly important. Draw the VSS line as wide as possible.
- Basically, make the GND part of the circuit board as broad as possible and keep the impedance low.
- There are two VBAT lines (not connected inside the IC).
a) VBAT (pin No. 12): Reference (low noise)
b) VBAT (pin No. 16): All others (semi-low noise)
- Connect CL3 at both pin No. 19 (VDDX) and pin No. 21 (VOUT3) if possible (for example, connect $6.8 \mu \mathrm{~F}$ at each pin).
- Do not use through holes at locations for connecting CL1 to CL3.
- Increasing CL1 makes the output more stable. If the DC/DC P output fluctuates due to ripple, and this causes VQERR to frequently exceed the DC/DC Q error amplifier threshold value, then DC/DC Q oscillates more than necessary and the DC/DC Q efficiency will decrease. Therefore, stabilizing the DC/DC P output will also improve DC/DC Q efficiency.
- Application Circuit

$\boldsymbol{\nabla}$ : small current VSS, $\frac{1}{\pi \mid}$ : large current VSS
Figure 21 Application Circuit Example

## - Precautions

- Mount external capacitors, diodes, coils, and other components as close as possible to the IC.
- The RS1, RS2, RT1, and RT2 values of the recommended peripheral parts are for $\mathrm{V}_{\text {Icon }}=1.6 \mathrm{~V}$. If a $\mathrm{V}_{\text {Icon }}$ value other than 1.6 V is used, the resistance values should be changed. The output voltage precision does not include external resistance dispersion.
- Characteristic ripple voltage and spike noise occur at the switching regulator. Since these are significantly affected by the coil and capacitor that are used, evaluate them using actual devices when the circuit is designed.
- CR1 and CR2 contribute to the stability of the VQERR pin potential and increase the efficiency of switching regulator Q. Although a capacitance value in the range from 1000 pF to $0.01 \mu \mathrm{~F}$ is recommended for CR1 and CR2, you should evaluate this value using an actual device.
- Make sure that the operating ambient temperature range of this IC is not exceeded due to switching transistor power dissipation (particularly at high temperature).

Figure 22 Power Dissipation of 24-pin TSSOP Package (Unmounted)

- Arrange parts so that the line to the VSS pin (indicated by the bold line in Figure 23) is as short as possible. If this line has resistance and inductance components, the VSS potential of the IC will fluctuate due to the switching current. If a potential difference is produced between the VSS of the CPU and the VSS of the IC, a malfunction may occur in the interface, and the electric volume may be reset.

Figure 23 VSS Line
Seiko Instruments Inc.

- When switching the output voltage by the electric volume, the soft start does not function. Note that an overshoot will occur when the output voltage increases by a large amount.
- When the internal impedance of the power supply (VBAT) is large, the S-8335 Series may not start up. Make sure that the internal impedance of the power supply used is sufficiently small when using this IC.
- Make sure that the potential of the VOUT1 pin does not exceed 20 V , which is the absolute maximum rating, when using this IC.
- Make the capacitance of VDIN, VCLK, and VSTR_B large enough to prevent noise and malfunctions.
- Seiko Instruments Inc. shall bear no responsibility for any patent infringement by a product that includes an IC manufactured by Seiko Instruments Inc. in relation to the method of using this IC in that product, the product specifications, or the destination country.

## - Characteristic Curves

1. Common characteristics (Unless otherwise specified, these graphs show typical data for $\mathrm{T}_{\mathrm{OPR}}=25^{\circ} \mathrm{C}$.)
