Application Engineering Support

EPSON offers the following services through their Sales and Marketing Network:

- Sales Technical Support
- Customer Training
- Design Assistance

Application Engineering Support

Engineering and Sales Support is provided by:

Japan
Seiko Epson Corporation
Electronic Devices Marketing Division
421-8, Hino, Hino-shi
Tokyo 191-8501, Japan
Tel: 042-587-5812
Fax: 042-587-5564
http://www.epson.co.jp

Hong Kong
Epson Hong Kong Ltd.
20/F., Harbour Centre
25 Harbour Road
Wanchai, Hong Kong
Tel: 2585-4600
Fax: 2827-4346

North America
Epson Electronics America, Inc.
150 River Oaks Parkway
San Jose, CA 95134, USA
Tel: (408) 922-0200
Fax: (408) 922-0238
http://www.eea.epson.com

Europe
Epson Europe Electronics GmbH
Riesstrasse 15
80992 Munich, Germany
Tel: 089-14005-0
Fax: 089-14005-110

Taiwan
Epson Taiwan Technology & Trading Ltd.
10F, No. 287
Nanking East Road
Sec. 3, Taipei, Taiwan
Tel: 02-2717-7360
Fax: 02-2712-9164

Singapore
Epson Singapore Pte., Ltd.

S1D13506 COLOR LCD/CRT/TV CONTROLLER

The S1D13506 is a color LCD/CRT/TV graphics controller interfacing to a wide range of CPUs and display devices. The S1D13506 architecture is designed to meet the low cost, low power requirements of the embedded markets, such as Mobile Communications, Hand-Held PC’s, and Office Automation.

The S1D13506 supports multiple CPUs, all LCD panel types, CRT, TV, and additionally provides a number of differentiating features. Products requiring digital camera input can take advantage of the directly supported WINNOV VideumCam™ digital interface. EPSON Independent Simultaneous Display allows the user to configure two different images on two different displays, while the SwivelView™, Hardware Cursor, Ink Layer, and BitBLT engine offer substantial performance benefits. These features, combined with the S1D13506’s Operating System independence, make it an ideal display solution for a wide variety of applications.

### FEATURES

- 16-bit EDO-DRAM or FPM-DRAM interface.
- Memory size options:
  - 512K bytes using one 256K×16 device.
  - 2M bytes using one 1M×16 device.
- Multiple CPU interface support.
- Resolutions up to:
  - 640x480 at a color depth of 16 bpp.
  - 800x600 at a color depth of 16 bpp.
- Display Support for:
  - 4/8/16-bit passive panels.
  - 9/12 TFT/D-TFD panels.
  - 18-bit TFT/D-TFD to a depth of 64K colors.
  - CRT.
- NTSC and PAL TV Output.
- SwivelView™: 90°, 180°, 270° hardware rotation of displayed image.
- EPSON Independent Simultaneous Display: displays different images on different displays.
- Virtual Display Support: displays images larger than the panel size through the use of panning.
- Hardware Cursor or full screen Ink Layer.
- 2D BitBLT Engine.
- WINNOV Videum® Cam digital camera interface.
- Software initiated Power Save Mode.
- Operating System Independent.

### SYSTEM BLOCK DIAGRAM
DESCRIPTION

Memory Interface
- 16-bit EDO-DRAM or FPM-DRAM interface.
- Addressable as a single linear address space.

CPU Interface
- Supports the following interfaces:
  - EPSON E0C33
  - NEC MIPS VR41xx
  - Hitachi SH-4/SH-3
  - PC Card (PCMCIA)
  - ISA bus
  - Philips MIPS PR31500/PR31700
  - Motorola M68xxxx
  - StrongARM (PC Card)
  - Motorola MPC821
  - Toshiba MIPS TX39xx
  - MPU with programmable READY
  - CPU Write buffer.

Display Support
  9/12-bit TFT/D-TFD. 
  18-bit TFT/D-TFD to a depth of 64K colors.
- CRT: Embedded RAMDAC for direct analog CRT.
- TV: Composite/S-Video TV output. 
  NTSC/PAL support.
  Flicker filter.
  Luminance filter.
  Chrominance filter.
- Maximum resolution of 800x600 at 16 bpp.

Power Down Modes
- Software initiated power save mode.
- LCD Power Sequencing.

Digital Video Camera Interface
- Built-in WINNOV Videum® Cam digital camera interface.

Display Modes
- 4/8/16 bit-per-pixel (bpp) support on LCD, CRT and TV.
- Up to 64 shades of gray on monochrome LCD panels using FRM and Dithering.
- Up to 64K colors on passive LCD, active matrix TFT/D-TFD, CRT and TV in 16 bpp modes.
- SwivelView™: 90°, 180°, 270° hardware rotation of displayed image.
- EPSON Independent Simultaneous Display (EISD): displays different images on different displays.
- Virtual Display Support: displays images larger than the panel size through the use of panning and scrolling.
- Hardware Cursor or full screen Ink Layer.

Acceleration
- 2D Engine including the following BitBLTs:
  - Write BLT
  - Move BLT
  - Solid Fill Pattern Fill
  - Transparent Write BLT
  - Transparent Move BLT
  - Read BLT
  - Color Expansion
  - Move BLT with Color Expansion

Operating Voltage
- 2.7 volts to 5.5 volts.

Package
- 128-pin QFP15.

# 1 Introduction

## 1.1 Scope

This is the Hardware Functional Specification for the S1D13506 Color LCD/CRT/TV Controller. Included in this document are timing diagrams, AC and DC characteristics, register descriptions, and power management descriptions. This document is intended for two audiences: Video Subsystem Designers and Software Developers.

This specification will be updated as appropriate. Please check the Epson Research and Development Website at http://www.erd.epson.com for the latest revision of this document before beginning any development.

We appreciate your comments on our documentation. Please contact us via email at documentation@erd.epson.com.

## 1.2 Overview Description

The S1D13506 is a color LCD/CRT/TV graphics controller interfacing to a wide range of CPUs and display devices. The S1D13506 architecture is designed to meet the low cost, low power requirements of the embedded markets, such as Mobile Communications, Hand-Held PC’s, and Office Automation.

The S1D13506 supports multiple CPUs, all LCD panel types, CRT, TV, and additionally provides a number of differentiating features. Products requiring digital camera input can take advantage of the directly supported WINNOV VideumCam™ digital interface. The EPSON Independent Simultaneous Display (EISD) capability allows the user to configure two different images on two different displays, while the SviwelView™, Hardware Cursor, Ink Layer, and BitBLT engine offer substantial performance benefits. These features, combined with the S1D13506’s Operating System independence, make it an ideal display solution for a wide variety of applications.
2 Features

2.1 Memory Interface

- 16-bit DRAM interface:
  - EDO-DRAM up to 40MHz data rate (80M Bytes/s).
  - FPM-DRAM up to 25MHz data rate (50M Bytes/s).

- Memory size options:
  - 512K bytes using one 256K×16 device.
  - 2M bytes using one 1M×16 device.

- A configuration register can be programmed to enhance performance by tailoring the memory control output timing to the DRAM device.

- The complete 2M byte display buffer address space is directly and contiguously available through the 21-bit address bus.

2.2 CPU Interface

- Supports the following interfaces:
  - Epson E0C33 (16-bit interface to 32-bit microprocessor).
  - Hitachi SH-4 bus interface.
  - Hitachi SH-3 bus interface.
  - MIPS/ISA.
  - Motorola MC68000 (16-bit interface to 16/32-bit microprocessor/microcontroller).
  - Motorola MC68030 (16-bit interface to 16/32-bit microprocessor/microcontroller).
  - Motorola PowerPC MPC82x (16-bit interface to 32-bit microprocessor).
  - MPU bus interface with programmable READY.
  - NEC MIPS VR41xx.
  - PC Card (PCMCIA).
  - Philips MIPS PR31500/31700.
  - Toshiba MIPS TX39xx.
  - StrongARM (PC Card).

- One-stage write buffer for minimum wait-state CPU writes.

- Registers are memory-mapped – the M/R# pin selects between display buffer and register address space.
2.3 Display Support

- 4/8-bit monochrome or 4/8/16-bit color LCD interface for single-panel, single-drive displays.
- 8-bit monochrome or 8/16-bit color LCD interface for dual-panel, dual-drive displays.
- Direct support for 9/12-bit TFT/D-TFD, 18-bit TFT/D-TFD is supported up to 64K colors.
- Direct support for CRT up to 64K colors using Embedded RAMDAC.
- Direct support for NTSC/PAL TV output using Embedded RAMDAC.

2.4 Display Modes

- 4/8/15/16 bit-per-pixel (bpp) color depths.
- Up to 64 shades of gray on monochrome passive LCD panels using Frame Rate Modulation (FRM) and Dithering.
- Up to 32K/64K colors in 15/16 bpp modes on color passive LCD panels using dithering.
- Up to 64K colors on TFT/D-TFD, CRT and TV.
- 4/8 bit-per-pixel color depths are mapped using three 256x4 Look-Up Tables (LUT) allowing 16/256 out of a possible 4096 colors.
- Separate LUTs for LCD and CRT/TV.
- 15/16 bit-per-pixel color depths are mapped directly, bypassing the LUT.
- Example Resolutions:
  - 320 x 240 at a color depth of 16 bpp.
  - 640 x 240 at a color depth of 16 bpp.
  - 640 x 480 at a color depth of 16 bpp.
  - 800 x 600 at a color depth of 16 bpp.

2.5 Display Features

- SwivelView™: 90°, 180°, 270° hardware rotation of display image.
- EPSON Independent Simultaneous Display (EISD): displays independent images on different displays (CRT or TV and passive or TFT/D-TFD panel).
- Virtual Display Support: displays images larger than the panel size through the use of panning and scrolling.
- Hardware Cursor/Ink Layer: separate 64x64x2 hardware cursor or 2-bit ink layer for both LCD and CRT/TV.
- Double Buffering/Multi-pages: for smooth animation and instantaneous screen update.
2.6 Clock Source

- Memory clock can be derived from CLKI or BUSCLK pin. It can be internally divided by 2.
- Pixel clock can be derived from CLKI, CLKI2, or BUSCLK pin. It can be internally divided by 2, 3 or 4.
- Bus clock can be BUSCLK or (BUSCLK)/2, i.e. a 2x clock may be used.

2.7 Acceleration

- 2D Engine including the following 2 ROP BitBLTs:
  - Write BLT.
  - Move BLT.
  - Solid Fill.
  - Pattern Fill.
  - Transparent Write BLT.
  - Transparent Move BLT.
  - Read BLT.
  - Color Expansion.
  - Move BLT with Color Expansion.

2.8 MediaPlug Interface

- Built-in WINNOV MediaPlug interface.
- Videum®Cam support at resolution of 320x240x256 color at 30fps.

2.9 Miscellaneous

- The memory data bus, MD[15:0], is used to configure the chip at power-on.
- Three General Purpose Input/Output pins, GPIO[3:1], are available if upper Memory Address pins are not required for asymmetric DRAM support.
- Power save mode is initiated by software.
- Operating voltage from 2.7 volts to 5.5 volts.
- 128-pin QFP15 surface mount package.
3 Typical System Implementation Diagrams

For the pin mapping of each system implementation, see Table 5-7: “CPU Interface Pin Mapping,” on page 40.

5.2 Pin Description

Key:

- **I** = Input
- **O** = Output
- **IO** = Bi-Directional (Input/Output)
- **A** = Analog
- **P** = Power pin
- **C** = CMOS level input
- **CD** = CMOS level input with pull down resistor (typical values of 50Ω/90Ω at 5V/3.3V respectively)
- **CS** = CMOS level Schmitt input
- **COx** = CMOS output driver, x denotes driver type (1=4/-4mA, 2=8/-8mA, 3=12/-12mA @ 5V)
- **TSx** = Tri-state CMOS output driver, x denotes driver type (1=4/-4mA, 2=8/-8mA, 3=12/-12mA @ 5V), x denotes driver type (1=4/-4mA, 2=8/-8mA, 3=12/-12mA @ 5V)
- **TSu** = TSx with pull up resistor (typical values of 100KΩ/180KΩ at 5V/3.3V respectively)
- **TSxD** = TSx with pull down resistor, x denotes driver type (1=4/-4mA, 2=8/-8mA, 3=12/-12mA @ 5V) (typical values of 100KΩ/180KΩ at 5V/3.3V)
- **CNx** = CMOS low-noise output driver, x denotes driver type (1=4/-4mA, 2=8/-8mA, 3=12/-12mA @ 5V)
- **CNxU** = CNx with pull up resistor, x denotes driver type (1=4/-4mA, 2=8/-8mA, 3=12/-12mA @ 5V)
- **CNxD** = CNx with pull down resistor, x denotes driver type (1=4/-4mA, 2=8/-8mA, 3=12/-12mA @ 5V)

5.2.1 Host Bus Interface

<table>
<thead>

| BUSCLK   | I    | 13    | C    | Hi-Z         | This pin inputs the system bus clock. It is possible to apply a 2x clock and divide it by 2 internally - see MD12 in *Summary of Configuration Options*.  
  - For SH-3/SH-4 Bus, this pin is connected to CKIO.  
  - For MC68K Bus 1, this pin is connected to CLK.  
  - For MC68K Bus 2, this pin is connected to CLK.  
  - For Generic Bus, this pin is connected to BCLK.  
  - For MIPS/ISA Bus, this pin is connected to CLK.  
  - For Philips PR31500/31700 Bus, this pin is connected to DCLKOUT.  
  - For Toshiba TX3912 Bus, this pin is connected to DCLKOUT.  
  - For PowerPC Bus, this pin is connected to CLKOUT.  
  - For PC Card (PCMCIA) Bus, this pin is connected to an external input clock source.  
  See Table 5-7: “CPU Interface Pin Mapping,” on page 40 for summary. See the respective AC Timing diagram for detailed functionality. |
| BS#      | I    | 6     | CS   | Hi-Z         | This is a multi-purpose pin:  
  - For SH-3/SH-4 Bus, this pin inputs the bus start signal (BS#).  
  - For MC68K Bus 1, this pin inputs the address strobe (AS#).  
  - For MC68K Bus 2, this pin inputs the address strobe (AS#).  
  - For Generic Bus, this pin is connected to VDD.  
  - For MIPS/ISA Bus, this pin is connected to VDD.  
  - For Philips PR31500/31700 Bus, this pin is connected to VDD.  
  - For Toshiba TX3912 Bus, this pin is connected to VDD.  
  - For PowerPC Bus, this pin inputs the Transfer Start signal (TS#).  
  - For PC Card (PCMCIA) Bus, this pin is connected to VDD.  
  See Table 5-7: “CPU Interface Pin Mapping,” on page 40 for summary. See the respective AC Timing diagram for detailed functionality. |
| RD/WR#   | I    | 10    | CS   | Hi-Z         | This is a multi-purpose pin:  
  - For SH-3/SH-4 Bus, this pin inputs the read write signal (RD/WR#). The S1D13506 needs this signal for early decode of the bus cycle.  
  - For MC68K Bus 1, this pin inputs the read write signal (R/W#).  
  - For MC68K Bus 2, this pin inputs the read write signal (R/W#).  
  - For Generic Bus, this pin inputs the read command for the upper data byte (RD1#).  
  - For MIPS/ISA Bus, this pin is connected to VDD.  
  - For Philips PR31500/31700 Bus, this pin inputs the even byte access enable signal (/CARDxCSL).  
  - For Toshiba TX3912 Bus, this pin inputs the even byte access enable signal (CARDxCSL*).  
  - For PowerPC Bus, this pin inputs the read write signal (RD/WR#).  
  - For PC Card (PCMCIA) Bus, this pin inputs the card enable 1 signal (CE1#).  
  See Table 5-7: “CPU Interface Pin Mapping,” on page 40 for summary. See the respective AC Timing diagram for detailed functionality. |

</tbody>
</table>

\(^a\)When the MD configuration at RESET# is set such that WAIT# can be tristated.  
\(^b\)When the MD configuration at RESET# is set such that WAIT# is always driven and active low.  
\(^c\)When the MD configuration at RESET# is set such that WAIT# is always driven and active high.
## 5.2.2 Memory Interface

**Table 5-2: Memory Interface Pin Descriptions**

<table>
<thead>
<tr>
<th>Pin Name</th>
<th>Type</th>
<th>Pin #</th>
<th>Cell</th>
<th>RESET# State</th>
<th>Description</th>
</tr>
</thead>
</table>
| LCAS#    | O    | 51    | CO1  | 1            | • For dual-CAS# DRAM, this is the column address strobe for the lower byte (LCAS#).  
• For single-CAS DRAM, this is the column address strobe (CAS#).  
See Table 5-8: “Memory Interface Pin Mapping,” on page 41 for summary. See Memory Interface Timing on page 70 for detailed functionality. |
| UCAS#    | O    | 52    | CO1  | 1            | This is a multi-purpose pin:  
• For dual-CAS# DRAM, this is the column address strobe for the upper byte (UCAS#).  
• For single-CAS# DRAM, this is the write enable signal for the upper byte (UWE#).  
See Table 5-8: “Memory Interface Pin Mapping,” on page 41 for summary. See Memory Interface Timing on page 70 for detailed functionality. |
| WE#      | O    | 53    | CO1  | 1            | • For dual-CAS# DRAM, this is the write enable signal (WE#).  
• For single-CAS# DRAM, this is the write enable signal for the lower byte (LWE#).  
See Table 5-8: “Memory Interface Pin Mapping,” on page 41 for summary. See Memory Interface Timing on page 70 for detailed functionality. |
| RAS#     | O    | 54    | CO1  | 1            | Row address strobe - see Memory Interface Timing on page 70 for detailed functionality. |
| MD[15:0] | IO   | 34, 36, 38, 40, 42, 44, 46, 48, 49, 47, 45, 43, 41, 39, 37, 35 | C/TS1D | Hi-Z (pull 0) | Bi-directional memory data bus.  
During reset, these pins are inputs and their states at the rising edge of RESET# are used to configure the chip - see Summary of Configuration Options on page 39. Internal pull-down resistors (typical values of 100KΩ/180KΩ at 5V/3.3V respectively) pull the reset states to 0. External pull-up resistors can be used to pull the reset states to 1.  
See Memory Interface Timing on page 70 for detailed functionality. |

**Note**

All GPIO pins default to input on reset and unless programmed otherwise, must be connected to either V SS or IO V DD if not used.

**Note**

1. AB0 is not used internally for these busses and must be connected to either V SS or V DD.

2. For further information on interfacing the S1D13506 to the PC Card bus, see *Interfacing to the PC Card Bus*, document number X25B-G-005-xx.

</tr>
</tbody>
</table>

**Note**

\(^1\) For MA9, MA10, and MA11 functionality see Table 5-10; “MA11, MA10, MA9, and DRDY Pin Mapping,” on page 43.

\(^2\) All GPIO pins default to input on reset and unless programmed otherwise, should be connected to either V\(_{SS}\) or IO V\(_{DD}\) if not used.
**Note**

DRDY and FPDAT[15:8] may be used by the MediaPlug interface when the MediaPlug is enabled. For MediaPlug Interface pin mapping, see Table 5-11:

**Note**

For FPDATxx to LCD interface hardware connections, refer to Section 7.5, “Display Interface” on page 81.
Note

1 Either DRDY or MA11 may be used for VMPEPWR (see Table 5-10: “MA11, MA10, MA9, and DRDY Pin Mapping”). If DRDY is required by the LCD interface and MA11 is required by the DRAM interface then VMPEPWR is not available.
5.5 CRT/TV Interface

The following figure shows external circuitry for the CRT/TV interface.

![Diagram of CRT/TV Interface](image)

**Figure 5-2: External Circuitry for CRT/TV Interface**

**Note**

Example implementation only, individual characteristics of components may affect actual IREF current.

7.1.2 Hitachi SH-4 Interface Timing

**Figure 7-2: Hitachi SH-4 Timing**

**Note**

BUSCLK cannot be divided by 2 in SH-4 interface mode. MD12 must be set to 0 (BUSCLK input is not divided).

**Note**

The SH-4 Wait State Control Register for the area in which the S1D13506 resides must be set to a non-zero value. The SH-4 read-to-write idle cycle transition must be set to a non-zero value (with reference to BUSCLK).
1. Two software WAIT states are required.
2. One software WAIT state is required.

Table 7-2: Hitachi SH-4 Timing

---
7.1.3 Hitachi SH-3 Interface Timing

**Figure 7-3: Hitachi SH-3 Timing**

**Note**
BUSCLK cannot be divided by 2 in SH-3 interface mode. MD12 must be set to 0 (BUSCLK input is not divided).

**Note**
The SH-3 Wait State Control Register for the area in which the S1D13506 resides must be set to a non-zero value.
1. Two software WAIT states are required when $f_{\text{CKIO}}$ is greater than 33MHz.
2. One software WAIT state is required when $f_{\text{CKIO}}$ is greater than 33MHz.

7.6 TV Timing

7.6.1 TV Output Timing

The overall NTSC and PAL video timing is shown in Figure 7-50: and Figure 7-51: respectively.

![Figure 7-50: NTSC Video Timing](image)

**Figure 7-50: NTSC Video Timing**
Figure 7-51: PAL Video Timing
1. \( t_1 = ((\text{REG}[053]\text{ bits}[5:0]) + 1) \times 8 - 7 \) (4 bpp, 8 bpp modes) 
   = \((\text{REG}[053]\text{ bits}[5:0]) + 1\) \times 8 - 5 \) (15/16 bpp modes)
2. \( t_5_{\text{NTSC}} = ((\text{REG}[052]\text{ bits}[5:0]) \times 8) + 6 \) - \((((\text{REG}[053]\text{ bits}[5:0]) + 1) \times 8) - 108 \) (4 bpp, 8 bpp modes) 
   = \((\text{REG}[052]\text{ bits}[5:0]) \times 8) + 6 \) - \((((\text{REG}[053]\text{ bits}[5:0]) + 1) \times 8) - 110 \) (15/16 bpp modes)
3. \( t_5_{\text{PAL}} = ((\text{REG}[052]\text{ bits}[5:0]) \times 8) + 7 \) - \((((\text{REG}[053]\text{ bits}[5:0]) + 1) \times 8) - 136 \) (4 bpp, 8 bpp modes) 
   = \((\text{REG}[052]\text{ bits}[5:0]) \times 8) + 7 \) - \((((\text{REG}[053]\text{ bits}[5:0]) + 1) \times 8) - 138 \) (15/16 bpp modes)
4. \( t_6_{\text{NTSC}} = (\text{REG}[052]\text{ bits}[5:0]) \times 8) + 6 \)
5. \( t_6_{\text{PAL}} = (\text{REG}[052]\text{ bits}[5:0]) \times 8) + 7 \)
6. \( t_7 = (\text{REG}[050]\text{ bits}[6:0]) + 1 \) \times 8

**Important:**

\( \text{REG}[050] \) and \( \text{REG}[052] \) must be programmed to satisfy the Line Period \((t_8)\).

For NTSC, \(((\text{REG}[050]\text{ bits}[6:0]) + 1) \times 8) + (((\text{REG}[052]\text{ bits}[5:0]) \times 8) + 6) = 910.\)

For PAL, \(((\text{REG}[050]\text{ bits}[6:0]) + 1) \times 8) + (((\text{REG}[052]\text{ bits}[5:0]) \times 8) + 7) = 1135.\)

   \( = \left(\text{REG}[059]\ b[6:0]\right) + 4.5 \) for field 2 and field 4

Important
REG[056], REG[057], and REG[058] must be programmed to satisfy the Frame Period (t5).
For NTSC, \( \left(\text{REG}[057]\ b[1:0], \text{REG}[056]\ b[7:0]\right) + 1 + \left(\text{REG}[058]\ b[6:0]\right) + 1 \times 2 + 1 = 525 \)
For PAL, \( \left(\text{REG}[057]\ b[1:0], \text{REG}[056]\ b[7:0]\right) + 1 + \left(\text{REG}[058]\ b[6:0]\right) + 1 \times 2 + 1 = 625. \)
7.7 MediaPlug Interface Timing

8 Registers

This section discusses how and where to access the S1D13506 registers. It also provides detailed information about the layout and usage of each register.

8.1 Initializing the S1D13506

Before programming the S1D13506 registers, the Register/Memory Select bit (REG[000h] bit 7) must be set.

8.1.1 Register/Memory Select Bit

At reset, the Register/Memory Select bit is set to 1. This means that only REG[000h] (read-only) and REG[001h] are accessible until a write to REG[001h] sets bit 7 to 0 making all registers and memory accessible. When debugging a new hardware design, this can sometimes give the appearance that the interface is not working, so it is important to remember to clear this bit before proceeding with debugging.

8.2 Register Mapping

The S1D13506 registers are memory-mapped. When the system decodes the input pins as CS# = 0 and M/R# = 0, the registers may be accessed. The register space is decoded by A20-A0.

When A20 = 1 the BitBLT data register ports are decoded allowing the system to access the display buffer through the 2D BitBLT engine using address lines A19-A0. When A20 = 0 and A12 = 0 the registers are decoded using A8-A0 as an index. When A20 = 0 and A12 = 1 the MediaPlug register ports are decoded using A11-A0.

The MediaPlug register ports are defined only when configuration input MD13 = 1 on reset. When MD13 = 0 on reset, A12 is always treated as 0 and the MediaPlug register space is not available - see Table 5-6: “Summary of Power-On/Reset Options,” on page 39.

Table 8-1: “Register Mapping with CS# = 0 and M/R# = 0” shows the decoding for each register type.

<table>
<thead>
<tr>
<th>Register Types (Range)</th>
<th>Address A20-A0 Decoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>BitBLT data registers (1M byte)</td>
<td>100000h to 1FFFFFh</td>

<td>MediaPlug registers (4K bytes)</td>
<td>1000h to 1FFh</td>
</tr>
<tr>
<td>Main Registers (512 bytes)</td>
<td>0 to 1FFh</td>
</tr>
</tbody>
</table>

Note

The registers may be aliased within the allocated register space. If aliasing is undesirable, the register space must be fully decoded.

</tbody>
</table>

bit 7  Register Memory Select
At reset, the Register/Memory Select bit is set to 1. This means that only REG[000h] (read-only) and REG[001h] are accessible until a write to REG[001h] sets bit 7 to 0 making all registers and memory accessible. When debugging a new hardware design, this can sometimes give the appearance that the interface is not working, so it is important to remember to clear this bit before proceeding with debugging.

bit 2  Reserved.
This bit must be set to 0.

bit 1  Reserved.
This bit must be set to 0.

bit 0  Reserved.
This bit must be set to 0.
8.3.2 General IO Pins Registers

</tr>
</tbody>
</table>

bit 3
GPIO3 Pin IO Configuration
When this bit = 1, GPIO3 is configured as an output pin.
When this bit = 0 (default), GPIO3 is configured as an input pin.

Note
Note that MD[7:6] must be properly configured at the rising edge of RESET# to enable GPIO3, otherwise GPIO3 will be used as MA[9] for the DRAM and this bit will have no hardware effect. (See Table 8-2: “MA[11:9]/GPIO[1:3] Pin Functionality”).

bit 2
GPIO2 Pin IO Configuration
When this bit = 1, GPIO2 is configured as an output pin.
When this bit = 0 (default), GPIO2 is configured as an input pin.

Note
Note that MD[14] and MD[7:6] must be properly configured at the rising edge of RESET# to enable GPIO2, otherwise GPIO2 will be used as MA[11] for the DRAM or as the MediaPlug VMPEPWR output and this bit will have no hardware effect. (See Table 8-2: “MA[11:9]/GPIO[1:3] Pin Functionality”).

bit 1
GPIO1 Pin IO Configuration
When this bit = 1, GPIO1 is configured as an output pin.
When this bit = 0 (default), GPIO1 is configured as an input pin.

Note
Note that MD[7:6] must be properly configured at the rising edge of RESET# to enable GPIO1, otherwise GPIO1 will be used as MA[10] for the DRAM and this bit will have no hardware effect. (See Table 8-2: “MA[11:9]/GPIO[1:3] Pin Functionality”).

</tbody>
</table>
bit 3  GPIO3 Pin IO Status
When GPIO3 is configured as an output, writing a 1 to this bit drives GPIO3 high and writing a 0 to this bit drives GPIO3 low.
When GPIO3 is configured as an input, a read from this bit returns the status of GPIO3.

Note
Note that MD[7:6] must be properly configured at the rising edge of RESET# to enable GPIO3, otherwise GPIO3 will be used as MA9 for the DRAM and this bit will have no hardware effect. (See Table 8-2: “MA[11:9]/GPIO[1:3] Pin Functionality”).

bit 2  GPIO2 Pin IO Status
When GPIO2 is configured as an output, writing a 1 to this bit drives GPIO2 high and writing a 0 to this bit drives GPIO2 low.
When GPIO2 is configured as an input, a read from this bit returns the status of GPIO2.

Note
Note that MD[14] and MD[7:6] must be properly configured at the rising edge of RESET# to enable GPIO2, otherwise GPIO2 will be used as MA11 for the DRAM or as the MediaPlug VMPEPWR output and this bit will have no hardware effect. (See Table 8-2: “MA[11:9]/GPIO[1:3] Pin Functionality”).

bit 1  GPIO1 Pin IO Status
When GPIO1 is configured as an output, writing a 1 to this bit drives GPIO1 high and writing a 0 to this bit drives GPIO1 low.
When GPIO1 is configured as an input, a read from this bit returns the status of GPIO1.

Note
Note that MD[7:6] must be properly configured at the rising edge of RESET# to enable GPIO1, otherwise GPIO1 will be used as MA10 for the DRAM and this bit will have no hardware effect. (See Table 8-2: “MA[11:9]/GPIO[1:3] Pin Functionality”).

</thead>
<tbody>
<tr>
<td>n/a n/a n/a MCLK Divide Select n/a n/a n/a MCLK Source Select</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

bit 4  MCLK Divide Select  
When this bit = 1, the internal memory clock frequency is half of the MCLK source frequency.  
When this bit = 0, the memory clock frequency is equal to the MCLK source frequency.  
The MCLK frequency should always be set to the maximum frequency allowed by the DRAM. This provides maximum performance and minimizes overall system power consumption.

bit 0  MCLK Source Select  
When this bit = 1, the source for the internal MCLK is derived from BUSCLK.  
When this bit = 0, the source for MCLK is derived from CLKI.

<table>
<thead>
<tr>
<th>MCLK Source Select</th>
<th>MCLK Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

**bits 5-0**

MOD Rate Bits [5:0]

For a non-zero value these bits specify the number of FPLINE between toggles of the MOD output signal (DRDY).

When these bits are all 0’s the MOD output signal toggles every FPFRAME. These bits are for passive LCD panels only.

---

</table>

**bits 6-0**

LCD Horizontal Display Width Bits [6:0]

These bits specify the LCD panel horizontal display width, in 8 pixel resolution.

Horizontal display width in number of pixels = ((ContentsOfThisRegister)+ 1) × 8

The Horizontal Display Width has certain limitations on the values that may be used for each type of LCD panel. Use of values that do not meet the limitations listed in the following table will result in undefined behavior.

---

**Table 8-16: Horizontal Display Width (Pixels)**

</tr>
</tbody>
</table>

**Note**

This register must be programmed such that REG[032h] ≥ 3 (32 pixels).
bits 4-0  LCD Horizontal Non-Display Period Bits [4:0]
These bits specify the LCD panel horizontal non-display period width in 8 pixel resolution.

Horiz. non-display period width in number of pixels = \((\text{ContentsOfThisRegister}) + 1) \times 8\)

Note
This register must be programmed such that REG[032h] ≥ 3 (32 pixels).

Note
For TFT/D-TFD only:
REG[034h] + 1 ≥ (REG[035h] + 1) + (REG[036h] bits 3-0 + 1)

TFT FPLINE Start Position Register
REG[035h]  RW

bits 4-0  TFT FPLINE Start Position Bits [4:0]
For TFT/D-TFD panel only, these bits specify the delay, in 8 pixel resolution, from the start of the horizontal non-display period to the leading edge of the FPLINE pulse.

For 4/8 bpp color depth:
FPLINE start position in number of pixels = \((\text{ContentsOfThisRegister}) \times 8 + 4\)

For 15/16 bpp color depth:
FPLINE start position in number of pixels = \((\text{ContentsOfThisRegister}) \times 8 + 6\)

Note
For TFT/D-TFD only:
REG[034h] + 1 ≥ (REG[035h] + 1) + (REG[036h] bits 3-0 + 1)

<th>n/a</th>
<th>n/a</th>
<th>SwivelView™ Enable Bit 1</th>
<th>n/a</th>
<th>LCD Bit-per-pixel Select Bit 2</th>
<th>LCD Bit-per-pixel Select Bit 1</th>
<th>LCD Bit-per-pixel Select Bit 0</th>
</tr>
</thead>
</table>

**bit 7**  
LCD Display Blank  
When this bit = 1, the LCD display pipeline is disabled and all LCD data outputs are forced to zero (i.e., the screen is blanked).  
When this bit = 0, the LCD display pipeline is enabled.

**Note**  
If a dual panel is used, the Dual Panel Buffer (REG[041h] bit 0) must be disabled (set to 1) before blanking the LCD display.
bit 4  
SwivelView™ Enable Bit 1
When this bit = 1, the LCD display image is rotated 180° clockwise. Please refer to Section 15, “SwivelView™” on page 200 for application and limitations. When this bit = 0, there is no hardware effect.
This bit in conjunction with SwivelView™ Enable Bit 0 achieves the following hardware rotations.

<table>
<thead>
<tr>
<th>SwivelView Enable Bits</th>
<th>SwivelView™ Modes</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Normal</td>
</tr>
<tr>
<td>SwivelView Enable Bit 0 (REG[1FCh] bit 6)</td>
<td>0</td>
</tr>
<tr>
<td>SwivelView Enable Bit 1 (REG[040h] bit 4)</td>
<td>0</td>
</tr>
</tbody>
</table>

bits 2-0  
LCD Bit-per-pixel Select Bits [2:0]
These bits select the color depth (bit-per-pixel) for the displayed data.

**Note**
15/16 bpp color depths bypass the LUT. Passive panels are supported up to 32K/64K colors (4096 colors if dithering disabled, see REG[041h] bit 1). TFT/D-TFD panels are supported up to 32K/64K colors.

**Table 8-20: LCD Bit-per-pixel Selection**

<table>
<thead>
<tr>
<th>Bit-per-pixel Select Bits [1:0]</th>
<th>Color Depth (bpp)</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>

</tr>
<tr>
<td>100</td>
<td>15 bpp</td>
</tr>
<tr>
<td>101</td>
<td>16 bpp</td>
</tr>
<tr>
<td>110-111</td>
<td>Reserved</td>
</tr>
</tbody>
</table>
bit 1  
Dithering Disable

When this bit = 1, dithering on the passive LCD panel for 15/16 bpp mode is disabled allowing a maximum of 4096 colors ($2^{12}$) or 16 gray shades.

When this bit = 0, dithering on the passive LCD panel for 15/16 bpp mode is enabled allowing a maximum of 64K colors ($2^{16}$) or 64 gray shades.

Note

This bit has no effect in 4/8 bpp modes where dithering is not supported.

All passive STN color panels are controlled using 3 bits for each pixel (RGB) for a total of 8 possible colors. LCD controllers use a combination of Frame Rate Modulation (FRM) and dithering to achieve more than 8 colors per pixel. FRM can achieve 16 shades of color for each RGB component resulting in a total of 4096 possible colors (16x16x16). Dithering uses a 4 pixel square formation and applies a set of 4 hard-coded patterns for each of the 16 shades of color. This expands the original 16 shades of color from the FRM logic to 64 shades per RGB component which results in 256K colors per pixel (64x64x64).

For the S1D13506, 16 bpp is arranged as 5-6-5 RGB. In this mode, when dithering is enabled, the LUT is bypassed and the original 16-bit data is used as a pointer into the 64 shades per color in the following manner.

(5-6-5 RGB)  32 possible Red, 64 possible Green, 32 possible Blue

This combination of FRM and dithering results in 256K colors/pixel, however, the 16 bpp limitation of the S1D13506 limits this to 64K colors/pixel.

bit 0  
Dual Panel Buffer Disable

This bit is used to disable the Dual Panel Buffer.

When this bit = 1, the Dual Panel Buffer is disabled.

When this bit = 0, the Dual Panel Buffer is enabled.

When a single panel is selected, the Dual Panel Buffer is automatically disabled and this bit has no effect.

The Dual Panel Buffer is needed to fully support dual panels. Disabling the Dual Panel Buffer will improve performance, reduce power consumption, and allow higher resolution/ color display modes than would otherwise be possible; however, disabling the Dual Panel Buffer will reduce image contrast and overall display quality. This mode is not normally used except in special circumstances such as simultaneous display on a CRT/TV and dual panel LCD. For details on Frame Rate Calculation, see Section 17.
REG[042h] bits 7-0  LCD Display Start Address Bits [19:0]

REG[043h] bits 7-0  This register forms the 20-bit address for the starting word of the LCD image in the display buffer.

REG[044h] bits 3-0  Note that this is a word address. An entry of 00000h into these registers represents the first word of display memory, an entry of 00001h represents the second word of the display memory, and so on.

REG[046h] bits 7-0  LCD Memory Address Offset Bits [10:0]

REG[047h] bits 2-0  These bits are the LCD display’s 11-bit address offset from the starting word of line “n” to the starting word of line “n + 1”.

A virtual image can be formed by setting this register to a value greater than the width of the display. The displayed image is a window into the larger virtual image.
**LCD Pixel Panning Register**

REG[048h]  

| bits 3-2 | Reserved.  
| Must be set to 0.  
| bits 1-0 | LCD Pixel Panning Bits [1:0]  
| This register is used to control the horizontal pixel panning of the LCD display. The display can be panned to the left by programming its respective Pixel Panning Bits to a non-zero value. This value represents the number of pixels panned. The maximum pan value is dependent on the display mode as shown in the table below.  

<table>
<thead>
<tr>
<th>Color Depth (bpp)</th>
<th>Screen 2 Pixel Panning Bits Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 bpp</td>
<td>Bits [1:0]</td>
</tr>
<tr>
<td>8 bpp</td>
<td>Bit 0</td>
</tr>
<tr>
<td>15/16 bpp</td>
<td>---</td>
</tr>
</tbody>
</table>

Smooth horizontal panning can be achieved by a combination of this register and the LCD Display Start Address register.

**LCD Display FIFO High Threshold Control Register**

REG[04Ah]  

| bits 5-0 | LCD Display FIFO High Threshold Bits [5:0]  
| These bits are used to optimize the display memory request arbitration. When this register is set to 00h, the threshold is automatically set in hardware. However, programming may be required if screen corruption is present (see Section 18.2, “Example Frame Rates” on page 215).  

**Note**  
This register does not need to be used in single display modes and may only be required in some display modes where two displays are active (see Section 16.2, “Bandwidth Limitation” on page 210).
bits 5-0 LCD Display FIFO Low Threshold Bits [5:0]
When this register is set to 00h, the threshold is automatically set in hardware. If it becomes necessary to adjust REG[04Ah] from its default value, then the following formula must be maintained:

\[ \text{REG}[04Bh] > \text{REG}[04Ah] \text{ and } \text{REG}[04Bh] \leq 3Ch \]

### 8.3.8 CRT/TV Configuration Registers

#### CRT/TV Horizontal Display Width Register

<table>
<thead>
<tr>
<th>n/a</th>
<th>n/a</th>

<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

bits 6-0 CRT/TV Horizontal Display Width Bits [6:0]
These bits specify the CRT/TV horizontal display width, in 8 pixel resolution.

Horizontal display width in number of pixels = \((\text{ContentsOfThisRegister} + 1) \times 8\)

#### CRT/TV Horizontal Non-Display Period Register

<table>
<thead>
<tr>
<th>n/a</th>
<th>n/a</th>
<th>CRT/TV Horizontal Non-Display Period Bit 5</th>
<th>CRT/TV Horizontal Non-Display Period Bit 4</th>
<th>CRT/TV Horizontal Non-Display Period Bit 3</th>
<th>CRT/TV Horizontal Non-Display Period Bit 2</th>
<th>CRT/TV Horizontal Non-Display Period Bit 1</th>
<th>CRT/TV Horizontal Non-Display Period Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

bits 5-0 CRT/TV Horizontal Non-Display Period Bits [5:0]
These bits specify the CRT/TV horizontal non-display period width in 8 pixel resolution.

Horizontal non-display period width in number of pixels = 
\((\text{ContentsOfThisRegister} + 1) \times 8\) for CRT mode
\((\text{ContentsOfThisRegister}) \times 8 + 6\) for TV mode with NTSC output
\((\text{ContentsOfThisRegister}) \times 8 + 7\) for TV mode with PAL output

**Note**
For CRT mode, the recommended minimum value which should be programmed into this register is 3 (32 pixels).

**Note**
\(\text{REG}[052h] + 1 \geq (\text{REG}[053h] + 1) + (\text{REG}[054h] \text{ bits } 3-0 + 1)\)
bits 5-0 CRT/TV HRTC Start Position Bits [5:0]
For CRT/TV, these bits specify the delay, in 8 pixel resolution, from the start of the horizontal non-display period to the leading edge of the HRTC pulse.

The following equations can be used to determine the HRTC start position in number of pixels for each display type:

HRTC start position in number of pixels =:

\[
\begin{align*}
&(\text{ContentsOfThisRegister}) \times 8 + 3 & &\text{for CRT with 4/8 bpp color depth} \\
&(\text{ContentsOfThisRegister}) \times 8 + 5 & &\text{for CRT in 15/16 bpp color depth} \\
&((\text{ContentsOfThisRegister}) + 1) \times 8 - 7 & &\text{for TV-NTSC in 4/8 bpp color depth} \\
&((\text{ContentsOfThisRegister}) + 1) \times 8 - 5 & &\text{for TV-NTSC in 15/16 bpp color depth} \\
&((\text{ContentsOfThisRegister}) + 1) \times 8 - 7 & &\text{for TV-PAL in 4/8 bpp color depth} \\
&((\text{ContentsOfThisRegister}) + 1) \times 8 - 5 & &\text{for TV-PAL in 15/16 bpp color depth}
\end{align*}
\]

Note
REG[052h] + 1 ≥ (REG[053h] + 1) + (REG[054h] bits 3-0 + 1)

---

<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>CRT/TV Bit-per-pixel Select Bit 2</td>
<td>CRT/TV Bit-per-pixel Select Bit 1</td>
<td>CRT/TV Bit-per-pixel Select Bit 0</td>
</tr>
</tbody>
</table>

**bit 7**

CRT/TV Display Blank
When this bit = 1 the CRT/TV display pipeline is disabled and all CRT/TV data outputs are forced to zero (i.e., the screen is blanked).
When this bit = 0 the CRT/TV display pipeline is enabled.

**bits 2-0**

CRT/TV Bit-per-pixel Select Bits [2:0]
These bits select the bit-per-pixel for the displayed data.

**Note**

15/16 bpp color depths bypass the LUT.

**Table 8-23: CRT/TV Bit-per-pixel Selection**

<table>
<thead>

</tbody>
</table>

REG[067h] bits 7-0 are CRT/TV Memory Address Offset Bits [19:16]

REG[067h] bits 3-0 are CRT/TV Memory Address Offset Bits [15:12]
**CRT/TV Pixel Panning Register**

REG[068h]  

<table>
<thead>
<tr>
<th>n/a</th>
<th>n/a</th>
<th>n/a</th>
<th>n/a</th>
<th>Reserved</th>
<th>Reserved</th>
<th>CRT/TV Pixel Panning Bit 1</th>
<th>CRT/TV Pixel Panning Bit 0</th>
</tr>
</thead>
</table>

**bits 3-2**  
 Reserved.  
 Must be set to 0.

**bits 1-0**  
 CRT/TV Pixel Panning Bits [1:0]  
 This register is used to control the horizontal pixel panning of the CRT/TV display. The display can be panned to the left by programming its respective Pixel Panning Bits to a non-zero value. This value represents the number of pixels panned. The maximum pan value is dependent on the display mode as shown in the table below.

**Table 8-24: CRT/TV Pixel Panning Selection**

<table>
<thead>
<tr>
<th>Color Depth (bpp)</th>
<th>Screen 2 Pixel Panning Bits Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 bpp</td>
<td>Bits [1:0]</td>
</tr>
<tr>
<td>8 bpp</td>
<td>Bit 0</td>
</tr>
<tr>
<td>15/16 bpp</td>
<td>---</td>
</tr>
</tbody>
</table>

Smooth horizontal panning can be achieved by a combination of this register and the CRT/TV Display Start Address register.

**CRT/TV Display FIFO High Threshold Control Register**

REG[06Ah]  

<table>
<thead>
<tr>
<th>n/a</th>
<th>n/a</th>
<th>CRT/TV Display FIFO High Threshold Bit 5</th>
<th>CRT/TV Display FIFO High Threshold Bit 4</th>
<th>CRT/TV Display FIFO High Threshold Bit 3</th>
<th>CRT/TV Display FIFO High Threshold Bit 2</th>
<th>CRT/TV Display FIFO High Threshold Bit 1</th>
<th>CRT/TV Display FIFO High Threshold Bit 0</th>
</tr>
</thead>
</table>

**bits 5-0**  
 CRT/TV Display FIFO High Threshold Bits [5:0]  
 These bits are used to optimize the display memory request arbitration. When this register is set to 00h, the threshold is automatically set in hardware. However, programming may be required if screen corruption is present (see Section 18.2, “Example Frame Rates” on page 215).

**Note**  
 This register does not need to be used in single display modes and may only be required in some display modes where two displays are active (see Section 16.2, “Bandwidth Limitation” on page 210).
CRT/TV Display FIFO Low Threshold Control Register

<table>
<thead>
<tr>
<th>REG[06Bh]</th>
<th>CRT/TV Display FIFO Low Threshold Bit 5</th>
<th>CRT/TV Display FIFO Low Threshold Bit 4</th>
<th>CRT/TV Display FIFO Low Threshold Bit 3</th>
<th>CRT/TV Display FIFO Low Threshold Bit 2</th>
<th>CRT/TV Display FIFO Low Threshold Bit 1</th>
<th>CRT/TV Display FIFO Low Threshold Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

bits 5-0 CRT/TV Display FIFO Low Threshold Bits [5:0]
When this register is set to 00h, the threshold is automatically set in hardware. If it becomes necessary to adjust REG[04Ah] from its default value, then the following formula must be maintained:

\[\text{REG}[04Bh] > \text{REG}[04Ah] \text{ and } \text{REG}[04Bh] \leq 3Ch\]

### 8.3.10 LCD Ink/Cursor Registers

<table>
<thead>
<tr>
<th>LCD Ink/Cursor Control Register</th>
<th>REG[070h]</th>
<th>LCD Ink/Cursor Mode Bit 1</th>
<th>LCD Ink/Cursor Mode Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

bits 1-0 LCD Ink/Cursor Control Bits [1:0]
These bits enable the LCD Ink/Cursor circuitry.

**Table 8-25: LCD Ink/Cursor Selection**

<table>
<thead>
<tr>
<th>LCD Ink/Cursor Bits [1:0]</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>10</td>
<td>Ink</td>
</tr>
<tr>
<td>11</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**Note**
While in Ink mode, the Cursor X & Y Position registers must be set to 00h.
**LCD Ink/Cursor Start Address Register**

REG[071h]

<table>
<thead>
<tr>
<th>LCD Ink/Cursor Start Address Bit 7</th>
<th>LCD Ink/Cursor Start Address Bit 6</th>
<th>LCD Ink/Cursor Start Address Bit 5</th>
<th>LCD Ink/Cursor Start Address Bit 4</th>
<th>LCD Ink/Cursor Start Address Bit 3</th>
<th>LCD Ink/Cursor Start Address Bit 2</th>
<th>LCD Ink/Cursor Start Address Bit 1</th>
<th>LCD Ink/Cursor Start Address Bit 0</th>
</tr>
</thead>
</table>

**bits 7-0**

Encoded bits defining the start address for the LCD Ink/Cursor. For Cursor modes, a start address of 0 should be valid for most applications. For Ink or special Cursor modes, the start address should be set at an address location that does not conflict with the display memory of Dual Panel Buffer, which always takes the top M memory locations in bytes, where

\[ M = (\text{Panel Height} \times \text{Panel Width} / 16) \times c \]

- \( c = 1 \) for monochrome, \( 4 \) for color panel.

**Note**

The effect of this register takes place at the next LCD vertical non-display period.

**Note**

See Section 10, “Display Buffer” on page 181 for display buffer organization.

---

**Table 8-26: LCD Ink/Cursor Start Address Encoding**

<table>
<thead>

<th>LCD Cursor X Position Bit 8</th>
</tr>
</thead>
</table>

**REG[073h] bit 7**

LCD Cursor X Sign

- When this bit = 1, it defines the LCD Cursor X Position register to be a negative number. The negative number shall not exceed 63 decimal.
- When this bit = 0, it defines the LCD Cursor X Position register to be a positive number.

**REG[072h] bits 7-0**

LCD Cursor X Position Bits [9:0]

A 10-bit register that defines the horizontal position of the LCD Cursor’s top left hand corner in pixel units. This register is only valid when Cursor has been selected in the LCD Ink/Cursor select registers.
REG[075h] bit 7 LCD Cursor Y Sign
When this bit = 1, it defines the LCD Cursor Y Position register to be a negative number. The negative number shall not exceed 63 decimal.
When this bit = 0, it defines the LCD Cursor Y Position register to be a positive number.

REG[074h] bits 7-0 LCD Cursor Y Position Bits [9:0]
REG[075h] bits 1-0 A 10-bit register that defines the vertical position of the LCD Cursor’s top left hand corner in pixel units. This register is only valid when Cursor has been selected in the LCD Ink/Cursor select registers.

Note
The effect of REG[072h] through REG[074h] takes place only after REG[075h] is written and at the next LCD vertical non-display period. The effect of REG[075h] takes place at the next LCD vertical non-display period.

LCD Ink/Cursor Blue Color 0 Bits[4:0]
These bits define the blue LCD Ink/Cursor color 0.

LCD Ink/Cursor Green Color 0 Bits[5:0]
These bits define the green LCD ink/Cursor color 0.
### LCD Ink/Cursor Red Color 0 Register

REG[078h]

CRT/TV Ink/Cursor FIFO High Threshold Register

<table>
<thead>
<tr>
<th>REG[08Eh]</th>
<th>RW</th>
</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

bits 5-0 CRT/TV Ink/Cursor FIFO High Threshold Bits [5:0]
These bits are used to optimize the display memory request arbitration for the Hardware Cursor/Ink Layer. When this register is set to 00h, the threshold is automatically set in hardware.

8.3.12 BitBLT Configuration Registers

| BitBLT Control Register 0
<table>
<thead>
<tr>
<th>REG[100h]</th>
<th>RW</th>
</tr>
</thead>
<tbody>
<tr>
<td>BitBLT Active Status</td>
<td>BitBLT FIFO Not Empty Status (RO)</td>
</tr>
</tbody>
</table>

bits 7 BitBLT Active Status
This register bit has two data paths, one for write, the other for read.
Write Data Path
When software writes a one to this bit, it will initiate the 2D operation.
Read Data Path
The read back of this register indicates the status of the 2D engine.
When a read from this bit = 1, the 2D engine is busy.
When a read from this bit = 0, the 2D engine is idle and is ready for the next operation.

Table 8-29: BitBLT Active Status

<table>
<thead>
<tr>
<th>BitBLT Active Status</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>Write</td>
<td>Read</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
bit 6  BitBLT FIFO Not-Empty Status  
This is a read-only status bit.  
When this bit = 1, the BitBLT FIFO has at least one data.  
When this bit = 0, the BitBLT FIFO is empty.  
To reduce system memory read latency, software can monitor this bit prior to a BitBLT read burst operation.  

The following table shows the number of data available in BitBLT FIFO under different status conditions.

<table>
<thead>
<tr>
<th>BitBLT FIFO Full Status (REG[100h] Bit 4)</th>
<th>BitBLT FIFO Half Full Status (REG[100h] Bit 5)</th>
<th>BitBLT FIFO Not Empty Status (REG[100h] Bit 6)</th>
<th>Number of Data available in BitBLT FIFO</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1 to 6</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>7 to 14</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>15 to 16</td>
</tr>
</tbody>
</table>

bit 5  BitBLT FIFO Half Full Status
This is a read-only status bit.  
Software can use this bit to optimize BitBLT write burst operations.  
When this bit = 1, the BitBLT FIFO is half full or greater than half full.  
When this bit = 0, the BitBLT FIFO is less than half full.

bit 4  BitBLT FIFO Full Status
This is a read-only status bit.  
Software can use this bit to optimize BitBLT write burst operations.  
When this bit = 1, the BitBLT FIFO is full.  
When this bit = 0, the BitBLT FIFO is not full.

bit 1  BitBLT Destination Linear Select
When this bit = 1, the Destination BitBLT is stored as a contiguous linear block of memory.  
When this bit = 0, the Destination BitBLT is stored as a rectangular region of memory.  
The BitBLT Memory Address Offset (REG[10Ch], REG[10Dh]) determines the address offset from the start of one line to the next line.

bit 0  BitBLT Source Linear Select
When this bit = 1, the Source BitBLT is stored as a contiguous linear block of memory.  
When this bit = 0, the Source BitBLT is stored as a rectangular region of memory.  
The BitBLT Memory Address Offset (REG[10Ch], REG[10Dh]) determines the address offset from the start of one line to the next line.

<td>Reserved</td>
</tr>
</tbody>
</table>

**LUT Address Bits [7:0]**
These 8 bits control a pointer into the Look-Up Tables (LUT). The S1D13506 has three 256-position, 4-bit wide LUTs, one for each of red, green, and blue – refer to Section 12, “Look-Up Table Architecture” on page 185 for details.

This register selects which LUT entry is read/write accessible through the LUT Data Register (REG[1E4h]). Writing the LUT Address Register automatically sets the pointer to the Red LUT. Accesses to the LUT Data Register automatically increment the pointer.

For example, writing a value 03h into the LUT Address Register sets the pointer to R[3]. A subsequent access to the LUT Data Register accesses R[3] and moves the pointer onto G[3]. Subsequent accesses to the LUT Data Register move the pointer onto B[3], R[4], G[4], B[4], R[5], etc.

**Note**
The RGB data is inserted into the LUT after the Blue data is written, i.e. all three colors must be written before the LUT is updated.
### Look-Up Table Data Register

<table>
<thead>
<tr>
<th>REG[1E4h]</th>

<td></td>
</tr>
<tr>
<td>When this bit = 0, the panel is powered up, or in transition of powering up or down.</td>
<td></td>
</tr>
</tbody>
</table>

**Note**
When this bit reads a 1, the system may safely shut down the LCD pixel clock source.
bit 0  
Memory Controller Power Save Status  
This bit indicates the power save state of the memory controller.  
When this bit = 1, the memory controller is powered down and is either in self refresh or no refresh mode.  
When this bit = 0, the memory controller is powered up and is either in CBR refresh or normal mode.  

Note  
When this bit reads a 1, the system may safely shut down the memory clock source.

8.3.15 Miscellaneous Registers

<table>
<thead>
<tr>
<th>CPU-to-Memory Access Watchdog Timer Register</th>
<th>RW</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG[1F4h]</td>
<td></td>
</tr>
<tr>
<td>n/a</td>
<td>n/a</td>
</tr>
</tbody>
</table>

bits 5-0  
CPU-to-Memory Access Watchdog Timer  
A non-zero value in this register enables the watchdog timer for CPU-to-memory access.  
When enabled, any CPU-to-memory access cycle will be completed successfully within a time determined by the following equation:  

Maximum CPU-to-memory access cycle time = (8n + 7) × T_{bclk} + 13 × T_{mclk}

where:  
n = A non-zero value in this register  
T_{bclk} = Bus clock period, or Bus clock period x 2 (if MD12 = 1, see Table 5-6: on page 39)  
T_{mclk} = Memory clock period

This function is required by some busses which time-out if the cycle duration exceeds a certain time period. This function is not intended to arbitrarily shorten the CPU-to-memory access cycle time in order gain higher CPU bandwidth. Doing so may significantly reduce the available display refresh bandwidth which may cause display corruption. This register does not affect CPU-to-register access or BitBLT access.
8.3.16 Common Display Mode Register

bit 6
SwivelView™ Enable Bit 0
When this bit = 1, the LCD and CRT display image is rotated 90° clockwise. Please refer to Section 15, “SwivelView™” on page 200 for application and limitations.
When this bit = 0, there is no hardware effect.
This bit in conjunction with SwivelView™ Enable Bit 1 achieves the following hardware rotations.

<table>
<thead>
<tr>
<th>SwivelView Enable Bits</th>
<th>SwivelView™ Modes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal</td>

</tr>
<tr>
<td>110</td>
<td>TV with flicker filter on</td>
</tr>
<tr>
<td>111</td>
<td>EISD (TV with flicker filter on and LCD)</td>
</tr>
</tbody>
</table>

Note
REG[018h] bit 7 must be set to 1 when the flicker filter is enabled.

Note
The Flicker Filter reduces the “flickering” effect seen on interlaced displays by averaging adjacent lines on the TV display. This “flickering” is caused by sharp vertical image transitions that occur over one line (1 vertical pixel). For example, one pixel high lines, edges of window boxes, etc. Flickering occurs because these high resolution lines are effectively displayed at half the refresh frequency due to interlacing.
8.3.17 MediaPlug Register Descriptions

The S1D13506 has built-in support for Winnov’s MediaPlug connection designed for video cameras. The following registers are used to control the connection and accept data from the camera. The MediaPlug registers decode A11-A0 and require A20 = 0 and A12 = 1. The MediaPlug registers are 16-bit wide. Byte access to the MediaPlug registers is not allowed. For further information, see Section 17, “MediaPlug Interface” on page 211.

Note
The MediaPlug control registers must not be accessed while Power Save Mode is enabled (REG[1F0h] bit 0 = 1).

bits 13-12
A read from these bits will always return 00b.
A write to these bits has no hardware effect.

bits 11-8 MediaPlug IC Revision (MediaPlug Parameter Rev)
The revision for this MediaPlug IC is “0011b”.
A write to these bits has no hardware effect.
bit 7  
  Cable Detected Status (MediaPlug Parameter Rstat)
  The cable detected status as determined by the MPD(1) pin.
  When this bit = 0, a MediaPlug cable is connected.
  When this bit = 1, a MediaPlug cable is not detected.
  A write to this bit has no hardware effect.

bit 6  
  A read from this bit will always return 0b.
  A write to this bit has no hardware effect.

bit 5  
  Remote Powered Status (MediaPlug Parameter Rstat)
  The remote powered status as determined by the RCTRL pin.
  When this bit = 0, the remote is not powered.
  When this bit = 1, the remote is powered and connected.
  A write to this bit has no hardware effect.

bit 4  
  A read from this bit will always return 0b.
  A write to this bit has no hardware effect.

bit 3  
  MediaPlug Interface Clock Enable (MediaPlug Parameter IC)
  When this bit = 0, the MediaPlug interface clock is enabled (default).
  When this bit = 1, the MediaPlug interface clock is disabled.

bit 2  
  MediaPlug Clock (MediaPlug Parameter MC)
  When this bit = 0, the MediaPlug cable clock is disabled (default).
  When this bit = 1, the MediaPlug cable clock is enabled.

bit 1  
  Power Enable to Remote (MediaPlug Parameter P)
  When this bit = 0, power to remote is off (default).
  When this bit = 1, power to remote is on.

bit 0  
  Watchdog Disable (MediaPlug Parameter W)
  When this bit = 0, the MediaPlug watchdog is enabled (default).
  When this bit = 1, the MediaPlug watchdog is disabled.

</tbody>
</table>

REG[1002h] bits 15-0  
MediaPlug CMD Bits [15:0]  
A 16-bit register for setting the MediaPlug commands. This register is handled differently for reads and writes. The following table shows the MediaPlug description of the CMD Register. See bit descriptions for details.

### Table 8-40: MediaPlug CMD Read/Write Descriptions

| Data | D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
|------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|
| Write | I[12:0] |   |   |   |   |   |   |   |   |   |   |   |   |   |
| Read  | D  | T  | I[10:0] |   |   |   |   |   |   |   |   |   |   |   |

**bit 15**  
Dirty Bit (MediaPlug Parameter D)  
This bit is set by the hardware when the command register is written.  
It is cleared by hardware by the following conditions:  
1. Remote-Reset (After this command has been acknowledged by remote.  
2. End_Stream (After this command has been acknowledged by remote.  
3. Write to DATA register if the CCC field is Write_Reg.  
4. Read to DATA register if the CCC field is Read_Reg.  
It is also set when the Remote Machine loses power or the cable is disconnected.

**bit 14**  
Timeout Bit (MediaPlug Parameter T)  
It is set when Watchdog is enabled and MediaPlug read or write cycle takes longer than 64, 128, 1024 cycles of MediaPlug clock depending on LCMD register settings.  
It is also set when the remote is not powered.  
It is cleared at the beginning of every command write by the host.

**bits 13-3**  
Index Field (MediaPlug Parameter I)  
This field is the address presented by the remote to the remote function. MediaPlug transmits the entire 16-bits of the first word of the command Register as written, but I12 (D15) and I11 (D14) are hidden from readback by the dirty bit and Watchdog error bit.
bit 2-0  Command Field (MediaPlug Parameter C)
Selects the command as follows:

Table 8-41: MediaPlug Commands

Data Register bits 15-0  BitBLT Data Bits [15:0]

A 16-bit register that specifies the BitBLT data. This register is loosely decoded from 100000h to 1FFFFEh.
9 2D BitBLT Engine

The S1D13506 has a built-in 2D BitBLT engine which increases the performance of Bit Block Transfers (BitBLT). This section will discuss the BitBLT engine design and functionality.

9.1 Functional Description

The 2D BitBLT engine is designed using a 16-bit architecture. It implements a 16-bit data bus and supports both 8 and 16 bit-per-pixel color depths.

The BitBLT engine supports rectangular and linear addressing modes for source and destination in a positive direction for all BitBLT operations except the move BitBLT which also supports in negative direction.

The BitBLT operations support byte alignment of all types. The BitBLT engine has a dedicated BitBLT IO access space allowing it to support multi-tasking applications. This allows the BitBLT engine to support simultaneous BitBLT and CPU read/write operations.

9.2 BitBLT Operations

Note
For details on the operation of the BitBLT registers, see Section 8.3.12, “BitBLT Configuration Registers” on page 161.

Write BitBLT

The Write BitBLT provides 16, two operand, ROP functions.

Move BitBLT

The Move BitBLT provides 16, two operand, ROP functions and is supported in both a positive and negative direction.

Read BitBLT

The Read BitBLT supports bit block transfers from the display buffer to the host. No ROP function is applied.

Solid Fill

The Solid Fill BitBLT fills a specified BitBLT area with a solid color as defined in the Foreground Color Register. In 8 bpp mode, only the low byte of the Foreground Color is used for solid fill.
Pattern Fill

The Pattern Fill BitBLT fills a specified BitBLT area with an 8 pixel by 8 line pattern in full color defined in off-screen display buffer. The pattern data has to be stored in a contiguous address (i.e. for 8 and 16 bpp, the pattern data will occupy 64 and 128 bytes respectively starting from the base address).

Any pixel within the 8x8 pattern can be used to start the fill area. The least significant bits of the source address start register are used to specify the starting pixel.

The 2D engine can detect the end of each line and continues from the beginning of the next line. When the last line of pattern is encountered, the first line of the pattern will be drawn on the following line.

Supports two full 16-bit operand ROP functions.

Note
The BitBLT operation Pattern Fill with ROP requires a BitBLT width \( \geq 2 \). The BitBLT width is set in REG[110h], REG[111h].

Transparent Pattern Fill

The Transparent Pattern Fill fills a specified BitBLT area with an 8 pixel by 8 line pattern in full color defined in off-screen display buffer. The pattern data has to be stored in a contiguous address (i.e. for 8 and 16 bpp, the pattern data will occupy 64 and 128 bytes respectively starting from the base address).

When the pattern color is equal to the key color, which is defined in Background Color Register, the destination area is not updated. In 8 bpp mode, only the low byte of the key color is used for comparison.

For this BitBLT no raster operation is applied.

Note
The BitBLT operation Pattern Fill with transparency requires a BitBLT width \( \geq 2 \). The BitBLT width is set in REG[110h], REG[111h].

Transparent Write BitBLT

The Transparent Write BitBLT supports bit block transfers from the host to display buffer.

When the source color is equal to key color, which is defined in Background Color Register, the destination area is not updated. In 8 bpp mode, only the low byte of the key color is used for comparison.

For this BitBLT no raster operation is applied.
**Transparent Move BitBLT**

The Transparent Move BitBLT supports bit block transfers from display buffer to display buffer in positive direction only.

When the source color is equal to key color, which is defined in Background Color Register, the destination area is not updated. In 8 bpp mode, only the low byte of key color is used for comparison.

For this BitBLT no raster operation is applied.

**Color Expansion**

The Color Expansion BitBLT expands the host’s monochrome data to 8 or 16 bpp color format.

A 1 expands to the color defined in the Foreground Color Register. In 8 bpp mode, only the low byte of the Foreground Color Register is used.

A 0 expands to the color defined in the Background Color Register. In 8 bpp mode, only the low byte of the Background Color Register is used. If background transparency is enabled, then the destination color will remain untouched.

The host will be continuously feeding a 16-bit data package. When the end of the line is reached, any unused bits will be discarded. The data for the next line will be taken from the next data package. The low byte write data will be used first for the operation. Each bit is serially expanded to the destination data starting from MSB (Bit 7) to LSB (Bit 0).

This BitBLT supports any bit alignment, but supports in a positive direction only.

**Move BitBLT with Color Expansion**

The Move BitBLT with Color Expansion expands off-screen source’s monochrome data to 8 or 16 bpp color format.

A 1 expands to the color defined in the Foreground Color Register.

A 0 expands to the color defined in the Background Color Register. If background transparency is enabled, then the destination color will remain untouched.

In 8 bpp mode, only the low byte of the Foreground Color Register and Background Color Register are used for color expansion. The low byte write data will be used first for the operation. Each bit is serially expanded to the destination data starting from MSB (Bit 7) to LSB (Bit 0).

This BitBLT supports byte alignment only and supports in a positive direction only.
10 Display Buffer

The system addresses the display buffer through the CS#, M/R#, and AB[20:0] input pins. When CS# = 0 and M/R# = 1, the display buffer is addressed by bits AB[20:0]. See the table below:

Table 10-1: S1D13506 Addressing

<table>
<thead>
<tr>
<th>CS#</th>
<th>M/R#</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Register access - see Section 8.2, “Register Mapping” on page 124.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• REG[000h] is addressed when AB[12:0] = 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• REG[001h] is addressed when AB[12:0] = 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• REG[n] is addressed when AB[12:0] = n</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Memory access: the 2M byte display buffer is addressed by AB[20:0]</td>
</tr>
<tr>
<td>1</td>
<td>X</td>
<td>S1D13506 not selected</td>
</tr>
</tbody>
</table>

The display buffer address space is always 2M bytes. However, the physical display buffer may be either 512K bytes or 2M bytes – see Section 5.3, “Summary of Configuration Options” on page 39.

A 512K byte display buffer is replicated in the 2M byte address space – see Figure 10-1: “Display Buffer Addressing,” on page 181.

The display buffer can contain an image buffer, one or more Ink Layer/Hardware Cursor buffers, and a Dual Panel Buffer.

Figure 10-1: Display Buffer Addressing
10.1 Image Buffer

The image buffer contains the formatted display mode data – see Section 11.1, “Display Mode Data Format” on page 183.

The displayed image(s) may occupy only a portion of this space; the remaining area may be used for multiple images – possibly for animation or general storage. Section 11, “Display Configuration” on page 183 for the relationship between the image buffer and the displayed image.

10.2 Ink Layer/Hardware Cursor Buffers

The Ink Layer/Hardware Cursor buffers contain formatted image data for the Ink Layer and Hardware Cursor.

There may be several Ink Layer/Hardware Cursor images stored in the display buffer but only one may be active at any given time.

For details see Section 14, “Ink Layer/Hardware Cursor Architecture” on page 196.

10.3 Dual Panel Buffer

In dual panel mode a buffer is required and allocated by hardware. With this Dual Panel Buffer enabled, the top of the display buffer is allocated to the Dual Panel Buffer. The size of the Dual Panel Buffer is a function of the panel resolution and whether the panel is color or monochrome:

\[
\text{Dual Panel Buffer Size (in bytes)} = \left( \text{panel width} \times \text{panel height} \right) \times \text{factor} / 16
\]

where factor:  
\(= 4\) for color panel  
\(= 1\) for monochrome panel

**Note**
Calculating the size of the Dual Panel Buffer is required to avoid overwriting the Hardware Cursor/Ink Layer buffer.

**Example 1:** For a 640x480 8 bpp color panel the Dual Panel Buffer size is 75K bytes. In a 512K byte display buffer, the Dual Panel Buffer resides from 6D400h to 7FFFFh. In a 2M byte display buffer, the Dual Panel Buffer resides from 1ED400h to 1FFFFFh.
11 Display Configuration

11.1 Display Mode Data Format

The following diagrams show the display mode data formats for a little endian system:

**Figure 11-1: 4/8/15/16 Bit-per-pixel Format Memory Organization**

**Note**
1. The Host-to-Display mapping shown here is for a little endian system.
2. For 15/16 bit-per-pixel formats, R_n, G_n, B_n represent the red, green, and blue color components.
11.2 Image Manipulation

The figure below shows how the screen image is stored in the image buffer and positioned on the LCD display. The screen image on the CRT/TVM is manipulated similarly. When EISD is enabled (see Section 16, “EPSON Independent Simultaneous Display (EISD)” on page 209), the images on the LCD and on the CRT/TVM are independent of each other.

- For LCD: REG[047h], REG[046h] defines the width of the virtual image.
  For CRT/TVM: REG[067h], REG[066h] defines the width of the virtual image.

- For LCD: REG[044h], REG[043h], REG[042h] defines the starting word of the displayed image.
  For CRT/TVM: REG[064h], REG[063h], REG[062h] defines the starting word of the displayed image.

- For LCD: REG[048h] defines the starting pixel within the starting word.
  For CRT/TVM: REG[068h] defines the starting pixel within the starting word.

- For LCD: REG[032h] defines the width of the LCD display.
  For CRT/TVM: REG[050h] defines the width of the CRT/TVM display.

- For LCD: REG[039h], REG[038h] defines the height of the LCD display.
  For CRT/TVM: REG[057h], REG[056h] defines the height of the CRT/TVM display.

![Image Manipulation Diagram](image.png)

Figure 11-2: Image Manipulation
12 Look-Up Table Architecture

The following depictions are intended to show the display data output path only.

12.1 Monochrome Modes

The green LUT is used for all monochrome modes.

4 Bit-Per-Pixel Monochrome Mode

![4 Bit-Per-Pixel Monochrome Mode Data Output Path](image)

*Figure 12-1: 4 Bit-Per-Pixel Monochrome Mode Data Output Path*
12.2 Color Modes

4 Bit-Per-Pixel Color

Figure 12-2: 4 Bit-Per-Pixel Color Mode Data Output Path
8 Bit-Per-Pixel Color

![Diagram showing 8 Bit-Per-Pixel Color Mode Data Output Path]

**Figure 12-3: 8 Bit-Per-Pixel Color Mode Data Output Path**

15/16 Bit-Per-Pixel Color Modes

The LUT is bypassed and the color data is directly mapped for these color depths—See “Display Configuration” on page 183.
13 TV Considerations

13.1 NTSC/PAL Operation

NTSC or PAL video is supported in either composite or S-video format. Filters may be enabled to reduce the distortion associated with displaying high resolution computer images on an interlaced TV display. The image can be vertically and horizontally positioned on the TV. Additionally, a dedicated Hardware Cursor (independent from the LCD display) is supported.

13.2 Clock Source

The required clock frequencies for NTSC/PAL are given in the following table:

<table>
<thead>
<tr>
<th>TV Format</th>
<th>Required Clock Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>NTSC</td>
<td>14.318180 MHz (3.579545 MHz subcarrier)</td>
</tr>
<tr>
<td>PAL</td>
<td>17.734475 MHz (4.43361875 MHz subcarrier)</td>
</tr>
</tbody>
</table>
13.3 Filters

When displaying computer images on a TV, several image distortions are likely to arise:

- cross-luminance distortion.
- cross-chrominance distortion.
- flickering.

These distortions are caused by the high-resolution nature of computer images which typically contain sharp color transitions, and sharp luminance transitions (e.g., high contrast one pixel wide lines and fonts, window edges, etc.). Three filters are available to reduce these distortions.

13.3.1 Chrominance Filter (REG[05Bh] bit 5)

The chrominance filter adjusts the color of the TV by limiting the bandwidth of the chrominance signal (reducing cross-luminance distortion). This reduces the “ragged edges” seen at boundaries between sharp color transitions. This filter is controlled using REG[05Bh] bit 5 and is most useful for composite video output.

13.3.2 Luminance Filter (REG[05Bh] bit 4)

The luminance filter adjusts the brightness of the TV by limiting the bandwidth of the luminance signal (reducing cross-chrominance distortion). This reduces the “rainbow-like” colors at boundaries between sharp luminance transitions. This filter is controlled using REG[05Bh] bit 4 and is most useful for composite video output.

13.3.3 Anti-flicker Filter (REG[1FCh] bits [2:1])

The “flickering” effect seen on interlaced displays is caused by sharp vertical image transitions that occur over one line (1 vertical pixel). For example, one pixel high lines, edges of window boxes, etc. Flickering occurs because these high resolution lines are effectively displayed at half the refresh frequency due to interlacing. The anti-flicker filter averages adjacent lines on the TV display to reduce flickering. This filter is controlled using the Display Mode register (REG[1FCh] bits [2:1]).

13.5 TV Image Display and Positioning

This section describes how to setup and position an image to be displayed on a TV. Figure 13-4: “NTSC/PAL Image Positioning,” on page 194 shows an image positioned on the TV display with the related programmable parameters. The TV display area is shaded.

The size of the display image determines the register values for the Horizontal Display Period, Horizontal Non-Display Period, Vertical Display Period, and Vertical Non-Display Period. The maximum and minimum values for these registers are given in Table 13-5: “Minimum and Maximum Values for NTSC/PAL”. The line period and frame period determined by these registers must also satisfy the following equations:

**NTSC:**

\[
(((\text{REG}[050] \text{ bits}[6:0]) + 1) \times 8) + (((\text{REG}[052] \text{ bits}[5:0]) \times 8) + 6) = 910
\]

\[
((\text{REG}[057] \text{ bits}[1:0]), (\text{REG}[056] \text{ bits}[7:0])) + 1) + ((\text{REG}[058] \text{ bits}[6:0]) + 1) \times 2 + 1 = 525
\]

**PAL:**

\[
(((\text{REG}[050] \text{ bits}[6:0]) + 1) \times 8) + (((\text{REG}[052] \text{ bits}[5:0]) \times 8) + 7) = 1135
\]

\[
((\text{REG}[057] \text{ bits}[1:0]), (\text{REG}[056] \text{ bits}[7:0])) + 1) + ((\text{REG}[058] \text{ bits}[6:0]) + 1) \times 2 + 1 = 625
\]

The HRTC Start Position and VRTC Start Position registers position the image horizontally and vertically. The maximum and minimum register values for these registers are given in Table 13-5: “Minimum and Maximum Values for NTSC/PAL”. Increasing the HRTC Start Position will move the image left, while increasing the VRTC Start Position will move the image up.
The maximum Horizontal and Vertical Display Widths shown in Table 13-5: “Minimum and Maximum Values for NTSC/PAL” include display areas that are normally hidden by the edges of the TV. The visible display dimensions are shown in Figure 13-5: “Typical Total Display and Visible Display Dimensions for NTSC and PAL,” on page 195 as a guideline. The actual visible display area for a particular TV may differ slightly from those dimensions given. Table 13-6: “Register Values for Example NTSC/PAL Images” lists register values for some example images.

13.6 TV Cursor Operation

See Section 14, “Ink Layer/Hardware Cursor Architecture” on page 196.
14 Ink Layer/Hardware Cursor Architecture

14.1 Ink Layer/Hardware Cursor Buffers

The Ink Layer/Hardware Cursor buffers contain formatted image data for the Ink Layer or Hardware Cursor. There may be several Ink Layer/Hardware Cursor images stored in the display buffer but only one may be active at any given time. The active Ink Layer/Hardware Cursor buffer is selected by the Ink/Cursor Start Address register (REG[071h] for LCD, REG[081h] for CRT/TV). This register defines the start address for the active Ink/Cursor buffer. The Ink/Cursor buffer must be positioned where it does not conflict with the image buffer and Dual Panel Buffer. The start address for the Ink/Cursor buffer is programmed as shown in the following table.

---

Table 14-1: Ink/Cursor Start Address Encoding

<table>
<thead>
<tr>
<th>Ink/Cursor Start Address Bits [7:0]</th>
<th>Start Address (Bytes)</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Display Buffer Size - 1024</td>
<td>This default value is suitable for a cursor when there is no Dual Panel Buffer.</td>
</tr>
</tbody>
</table>
| n = 255...1                        | Display Buffer Size - (n × 8192) | These positions can be used to:  
  • position an Ink buffer at the top of the display buffer;  
  • position an Ink buffer between the image and Dual Panel Buffers;  
  • position a Cursor buffer between the image and Dual Panel Buffers;  
  • select from a multiple of Cursor buffers. |

---

The Ink/Cursor image is stored contiguously. The address offset from the starting word of line \( n \) to the starting word of line \( n+1 \) is calculated as follows:

- LCD Ink Address Offset (words) = REG[032h] + 1
- CRT/TV Ink Address Offset (words) = REG[050h] + 1
- LCD or CRT/TV Cursor Address Offset (words) = 8
14.2 Ink/Cursor Data Format

The Ink/Cursor image is always 2 bit-per-pixel. The following diagram shows the Ink/Cursor data format for a little endian system.

![Figure 14-1: Ink/Cursor Data Format](image)

The image data for pixel n, \((A_n, B_n)\), selects the color for pixel n as follows.

<table>
<thead>
<tr>
<th>((A_n, B_n))</th>
<th>Color</th>
<th>Comments</th>
</tr>
</thead>

<td>Inverted Background</td>
<td>Ink/Cursor is transparent – show inverted background</td>
</tr>
</tbody>
</table>
14.3 Ink/Cursor Image Manipulation

14.3.1 Ink Image

The Ink image should always start at the top left pixel, i.e. Cursor X Position and Cursor Y Position registers should always be set to zero. The width and height of the ink image are automatically calculated to completely cover the display.

14.3.2 Cursor Image

The Cursor image size is always 64 x 64 pixels. The Cursor X Position and Cursor Y Position registers specify the position of the top left pixel. The following diagram shows how to position an unclipped cursor.

```
Figure 14-2: Unclipped Cursor Positioning
```

where

For LCD:

\[
x = \text{(REG}[073h] \text{ bits [1:0]}, \text{REG}[072h]) \text{ and } \text{REG}[073h] \text{ bit 7} = 0
\]

\[
y = \text{(REG}[075h] \text{ bits [1:0]}, \text{REG}[074h]) \text{ and } \text{REG}[075h] \text{ bit 7} = 0
\]

For CRT/TV:

\[
x = \text{(REG}[083h] \text{ bits [1:0]}, \text{REG}[082h]) \text{ and } \text{REG}[083h] \text{ bit 7} = 0
\]

\[
y = \text{(REG}[085h] \text{ bits [1:0]}, \text{REG}[084h]) \text{ and } \text{REG}[085h] \text{ bit 7} = 0
\]

The following diagram shows how to position a cursor that is clipped at the top and left sides of the display.
Figure 14-3: Clipped Cursor Positioning

where

For LCD:
\[
x = (\text{REG}[073h] \text{ bits } [1:0], \text{REG}[072h]) \leq 63 \text{ and } \text{REG}[073h] \text{ bit } 7 = 1
\]
\[
y = (\text{REG}[075h] \text{ bits } [1:0], \text{REG}[074h]) \leq 63 \text{ and } \text{REG}[075h] \text{ bit } 7 = 1
\]

For CRT/TV:
\[
x = (\text{REG}[083h] \text{ bits } [1:0], \text{REG}[082h]) \leq 63 \text{ and } \text{REG}[083h] \text{ bit } 7 = 1
\]
\[
y = (\text{REG}[085h] \text{ bits } [1:0], \text{REG}[084h]) \leq 63 \text{ and } \text{REG}[085h] \text{ bit } 7 = 1
\]
15 SwivelView™

15.1 Concept

Most computer displays are refreshed in landscape – from left to right and top to bottom. Computer images are stored in the same manner. SwivelView™ is designed to rotate the displayed image on an LCD by 90°, 180°, or 270° in a clockwise direction. 90° rotation is also available on CRT.

The rotation is done in hardware and is transparent to the user for all display buffer reads and writes. By processing the rotation in hardware, SwivelView™ offers a performance advantage over software rotation of the displayed image.

15.2 90° SwivelView™

90° SwivelView™ uses a 1024 × 1024 pixel virtual window. The following figures show how the display buffer memory map changes in 90° SwivelView™. The display is refreshed in the following sense: C–A–D–B. The application image is written to the S1D13506 in the following sense: A–B–C–D. The S1D13506 rotates and stores the application image in the following sense: C–A–D–B, the same sense as display refresh.

The user can read/write to the display buffer naturally, without the need to rotate the image first in software. The registers that control the panning and scrolling of the panel window are designed for a landscape window. However, it is still possible to pan and scroll the portrait window in 90° SwivelView™, but the user must program these registers somewhat differently (See Section 15.2.1, “Register Programming” on page 201).
15.2.1 Register Programming

**Enabling 90° Rotation on CPU Read/Write to Display Buffer**

Set SwivelView™ Enable bit 0 to 1. All CPU accesses to the display buffer are translated to provide 90° clockwise rotation of the display image. SwivelView™ Enable bit 1 should be set to 0.

**Memory Address Offset**

The LCD/CRT Memory Address Offset register (REG[046h], REG[047h] for LCD, or REG[066h], REG[0667h] for CRT) must be set for a 1024 pixel offset:

---

Note

- W is the width of the LCD panel/CRT in number of pixels, (or the height of the portrait window in number of lines).
- H is the height of the LCD panel/CRT in number of lines, (or the width of the portrait window in number of pixels).

Note

The image must be written with a 1024 pixel offset between adjacent lines (1024 bytes for 8 bpp mode or 2048 bytes for 15/16 bpp mode) and the display start address must be calculated (see below).
LCD/CRT Memory Address Offset (words)
\[ \begin{align*}
&= 1024 \quad \text{for 15/16 bpp mode} \\
&= 512 \quad \text{for 8 bpp mode}
\end{align*} \]

**Display Start Address**

As seen in Figure 15-1: “Relationship Between Screen Image and 90° Rotated Image in the Display Buffer,” on page 201, the Display Start Address is determined by the location of the image corner “C”, and it is generally non-zero. The LCD/CRT Display Start Address register (REG[042h], REG[043h], REG[044h] for LCD, or REG[062h], REG[063h], REG[064h] for CRT) must be set accordingly.

LCD/CRT Display Start Address (words)
\[ \begin{align*}
&= (1024 - W) \quad \text{for 15/16 bpp mode} \\
&= (1024 - W) / 2 \quad \text{for 8 bpp mode}
\end{align*} \]

where W is the width of the panel in number of pixels.

**Horizontal Panning**

Horizontal panning is achieved by changing the LCD/CRT Display Start Address register:

- Increase/decrease LCD/CRT Display Start Address register by 1024 (15/16 bpp mode) or 512 (8 bpp mode) pans the display window to the right/left by 1 pixel.

The amount the display window can be panned to the right is limited to 1024 pixels and limited by the amount of physical memory installed.

**Vertical Scrolling**

Vertical scrolling is achieved by changing the LCD/CRT Display Start Address register and/or the LCD/CRT Pixel Panning register:

- Increment/decrement LCD/CRT Display Start Address register in 8 bpp mode scrolls the display window up/down by 2 lines.
- Increment/decrement LCD/CRT Display Start Address register in 15/16 bpp mode scrolls the display window up/down by 1 line.
- Increment/decrement LCD/CRT Pixel Panning register in 8 bpp mode scrolls the display window up/down by 1 line.
15.2.2 Physical Memory Requirement

Because the user must now deal with a 1024×1024 virtual display, the amount of image buffer required for a particular display mode has increased. The minimum amount of image buffer required is:

Minimum Required Image Buffer (bytes)

\[
\begin{align*}
= (1024 \times H) \times 2 & \quad \text{for 15/16 bpp mode} \\
= (1024 \times H) & \quad \text{for 8 bpp mode}
\end{align*}
\]

where \( H \) is the height of the panel in number of lines.

This minimum amount is required to display a 90° SwivelView™ image without panning; scrolling, however, is permissible. The degree an image can be panned depends on the amount of physical memory installed and how much of that is used by the Dual Panel Buffer, Ink Layer, or Hardware Cursor. An image cannot be panned outside the 1024×1024 virtual display. Often it cannot be panned within the entire virtual display because part of the virtual display memory may be taken up by the Dual Panel Buffer, Ink Layer, Hardware Cursor, or even the CRT/TV display buffer.

The Dual Panel Buffer is used for dual panel mode. Its memory requirement is:

Dual Panel Buffer (bytes)

\[
\begin{align*}
=(W \times H) / 4 & \quad \text{for color mode} \\
=(W \times H) / 16 & \quad \text{for monochrome mode}
\end{align*}
\]

where \( W \) is the width of the panel in number of pixels, and \( H \) is the height of the panel in number of lines.

The Dual Panel Buffer is always located at the end of the physical memory.

The Hardware Cursor or Ink Layer also takes up memory. If this memory is > 1KB, it must be located at an 8KB boundary, otherwise it may be located at the last 1KB area. The Hardware Cursor or Ink Layer must not overlap the image buffer or the Dual Panel Buffer.

The following table summarizes the DRAM size requirement for 90° SwivelView™ for different panel sizes and display modes. Note that DRAM size for the S1D13506 is limited to either 512K byte or 2M byte. The calculation is based on the minimum required image buffer size and the Dual Panel Buffer size. The Hardware Cursor/Ink Layer may or may not fit within this minimum DRAM configuration – this is noted in the table. The hardware cursor requires only 1KB of memory and so may resides at the last 1KB area if there is no Dual Panel Buffer, otherwise it must reside at an 8KB boundary. The 2-bit ink layer requires \((W \times H) / 4\) bytes of memory; it must reside at an 8KB boundary. The table shows only one possible Hardware Cursor/Ink Layer location – at the highest possible location without interfering with the Dual Panel Buffer. It is also assumed that CRT/TV is not used.
### 15.2.3 Limitations

The following limitations apply to 90° SwivelView™:

- Only 8/15/16 bpp modes are supported – 4 bpp mode is not supported.
- Hardware cursor and ink images are not rotated – software rotation must be used. SwivelView™ Enable bit 0 must be set to 0 when the user is accessing the Hardware Cursor or the Ink Layer buffer.
- 90° SwivelView™ does not support BitBLTs.

---

Where KB = 1024 bytes and MB = 1024KB
15.3 180° SwivelView™

180° SwivelView™ is accomplished by fetching the display buffer image in the reverse address direction, starting at the bottom-right corner of the image. Unlike 90° SwivelView™, the 180° SwivelView™ image is not rotated in the display buffer. The image is simply displayed 180° clockwise rotated. Furthermore, a virtual window is not required and all color depths (4/8/15/16 bpp) are supported.

15.3.1 Register Programming

Reverse Display Buffer Fetching Address Direction

Set SwivelView™ Enable bit 1 to 1. During screen refresh, the direction of the address for display buffer fetching is reversed. This setting does not affect CPU to display buffer access in any way. SwivelView™ Enable bit 0 should be set to 0.

Display Start Address

The Display Start Address must be programmed to be at the bottom-right corner of the image, since the display is now refreshed in the reverse direction. The LCD Display Start Address register (REG[042h], REG[043h], REG[044h]) must be set accordingly.

\[
\text{LCD Display Start Address (words)} = \begin{cases} 
(MA\text{\_Offset} \times \text{H}) - (M\text{A\_Offset} - \text{W}) - 1 & \text{for 15/16 bpp mode} \\
(MA\text{\_Offset} \times \text{H}) - (M\text{A\_Offset} - \text{W}/2) - 1 & \text{for 8 bpp mode} \\
(MA\text{\_Offset} \times \text{H}) - (M\text{A\_Offset} - \text{W}/4) - 1 & \text{for 4 bpp mode}
\end{cases}
\]

where \( \text{H} \) is the height of the panel in number of lines, \( \text{W} \) is the width of the panel in number of pixels, and \( \text{MA\_Offset} \) is the LCD Memory Address Offset.

Horizontal Panning

Horizontal panning works in the same way as when SwivelView™ is not enabled, except that the effect of the LCD Pixel Panning register is reversed:

- Increment/decrement LCD Display Start Address register pans the display window to the right/left.
- Increment/decrement LCD Pixel Panning register pans the display window to the left/right.

Vertical Panning

Vertical panning works in the same way as when SwivelView™ is not enabled:

- Increase/decrease LCD Display Start Address register by one memory address offset scrolls the display window down/up by 1 line.
15.3.2 Limitations

The following limitations apply to 180° SwivelView™:

- Hardware Cursor and Ink Layer images are not rotated – software rotation must be used.
- CRT/TV mode is not supported.
- 180° SwivelView™ does not support all BitBLTs.

15.4 270° SwivelView™

270° SwivelView™ is a combination of 90° SwivelView™ and 180° SwivelView™. The image stored in the display buffer is 90° rotated, and the image is further 180° rotated during screen refresh, resulting in a 270° rotated display image. The user must use a 1024 × 1024 pixel virtual window as in 90° SwivelView™. See Figure 15-1: “Relationship Between Screen Image and 90° Rotated Image in the Display Buffer,” on page 201.

15.4.1 Register Programming

Enabling 90° Rotation on CPU Read/Write to Display Buffer

Set SwivelView™ Enable bit 0 to 1. All CPU access to the display buffer is translated to provide 90° clockwise rotation of the display image.

Reverse Display Buffer Fetching Address Direction

Set SwivelView™ Enable bit 1 to 1. During screen refresh, the direction of the address for display buffer fetching is reversed. This setting does not affect CPU to display buffer access in any way.

Memory Address Offset

The LCD Memory Address Offset register (REG[046h], REG[047h]) must be set for a 1024 pixel offset.

LCD Memory Address Offset (words)

\[
\begin{align*}
= 1024 & \quad \text{for 15/16 bpp mode} \\
= 512 & \quad \text{for 8 bpp mode}
\end{align*}
\]
Display Start Address

The Display Start Address must be programmed to be at the bottom-right corner of the image, since the display is now refreshed in the reverse direction. The LCD Display Start Address register (REG[042h], REG[043h], REG[044h]) must be set accordingly.

\[
\text{LCD Display Start Address (words)} = ((\text{LCD Memory Address Offset}) \times H) - 1
\]

where \( H \) is the height of the panel in number of lines.

Horizontal Panning

Horizontal panning is achieved by changing the LCD Display Start Address register. It works in the same way as in 90° SwivelView™ mode:

- Increase/decrease LCD Display Start Address register by 1024 (15/16 bpp mode) or 512 (8 bpp mode) pans the display window to the right/left by 1 pixel.

The amount the display window can be panned to the right is limited to 1024 pixels and limited by the amount of physical memory installed.

Vertical Scrolling

Vertical scrolling is achieved by changing the LCD Display Start Address register and/or the LCD Pixel Panning register. It works in the same way as in 90° SwivelView™ mode, except that the effect of the LCD Pixel Panning register is reversed:

- Increment/decrement LCD Display Start Address register in 8 bpp mode scrolls the display window up/down by 2 lines.
- Increment/decrement LCD Display Start Address register in 15/16 bpp mode scrolls the display window up/down by 1 line.
- Increment/decrement LCD Pixel Panning register in 8 bpp mode scrolls the display window down/up by 1 line.

15.4.2 Physical Memory Requirement

270° SwivelView™ mode has the same physical memory requirement as in 90° SwivelView™ mode.
15.4.3 Limitations

The following limitations apply to 270° SwivelView™:

- Only 8/15/16 bpp modes are supported – 4 bpp mode is not supported.

- Hardware Cursor and Ink Layer images are not rotated – software rotation must be used. SwivelView™ Enable bit 0 must be set to 0 when the user is accessing the Hardware Cursor or the Ink Layer memory.

- CRT/TV mode is not supported. SwivelView™ Enable bit 0 must be set to 0 when the user is accessing the CRT/TV display buffer.

- 270° SwivelView™ does not support BitBLTs.
16 EPSON Independent Simultaneous Display (EISD)

16.1 Introduction

EPSON Independent Simultaneous Display (EISD) allows the S1D13506 to display independent images on two different displays (LCD panel and CRT or TV). The LCD panel timings and mode setup are programmed through the Panel Configuration Registers (REG[03Xh]) and the LCD Display Mode Registers (REG[04Xh]). The CRT/TV timings and mode setup are programmed through the CRT/TV Configuration Registers (REG[05Xh]) and the CRT/TV Display Mode Registers (REG[06Xh]). The Ink Layer or Hardware Cursor can also be independently controlled on the two displays. The LCD Ink/Cursor Registers (REG[07Xh]) control the Ink/Cursor on the LCD display; the CRT/TV Ink/Cursor Registers (REG[08Xh]) control the Ink/Cursor on the CRT or TV. Each display uses its own Look-Up Table (LUT), although there is only one set of LUT Registers (REG[1E0h], REG[1E2h], REG[1E4h]). Use the LUT Mode Register (REG[1E0h]) to select access to the LCD and/or CRT/TV LUTs.

The pixel clock source for the two displays may also be independent. Use the Clock Configuration Registers (REG[014h], REG[018h]) to select the LCD pixel clock source and the CRT/TV pixel clock source, respectively. Typically, CLKI2 is used for the CRT/TV display, while CLKI is used for the LCD display. Memory clock may come from CLKI or BUSCLK.

To display different images on the LCD and CRT/TV, the two images should reside in non-overlapping areas of the display buffer, and the display start addresses point to the corresponding areas. The display buffer is mapped to the CPU address AB[20:0] linearly.

Example 1: Assuming a 2M byte display buffer, the LCD image may locate in the first 1M byte of the display buffer (AB[20:0] = 000000h-0FFFFFh), and the CRT/TV image may locate in the second 1M byte of the display buffer (AB[20:0] = 100000h-1FFFFFh).

The LCD and CRT/TV may display identical images by setting the display start addresses for the LCD and the CRT/TV to the same address. In this case only one image is needed in the display buffer. However, the display pipelines are still independent so the same image is fetched twice from the display buffer; once for the LCD refresh and once for the CRT/TV refresh.
16.2 Bandwidth Limitation

When EISD is enabled, the LCD and CRT/TV displays must share the total bandwidth available to the S1D13506. The result is that display modes with a high resolution or color depth may not be supported. In some cases, Ink Layers may not be possible on one or both of the displays. EISD increases the total demand for display refresh bandwidth and reduces CPU bandwidth, resulting in lower CPU performance.

In a few cases when EISD is enabled, the default LCD and CRT/TV Display FIFO High Threshold Control register values are not optimally set, causing display problems with one or both of the displays. This condition may be corrected by adjusting the values of the LCD and CRT/TV Display FIFO High Threshold Control registers (REG[04Ah] for LCD and REG[06Ah] for CRT/TV).

When the FIFO High Threshold Control register is set to 00h (default), the following settings are used:

- 11h for 4 bpp mode
- 21h for 8 bpp mode
- 23h for 15/16 bpp mode

Changing this register to a non-zero value sets the high threshold FIFO level to this value. This register may not exceed 59 decimal. The high threshold FIFO level controls how often display fetch requests are issued by the FIFO. In general, a higher high threshold FIFO level increases the bandwidth to that display pipe, and a lower level reduces it.

Most display problems may be corrected by increasing the associated high threshold FIFO level for that display. However, because the total available bandwidth is fixed, this change may create display problem for the other display. In this case, reducing the high threshold FIFO level for the other display instead may work. Sometimes, a combination of these two methods is required. Correcting EISD display problems by adjusting the FIFO High Threshold Control registers is mostly a trial-and-error process. While the user is free to experiment with these registers, recommended FIFO level settings for some of the more common EISD modes requiring non-default FIFO level settings are listed in Section 18.2, “Example Frame Rates” on page 215.
17 MediaPlug Interface

Winnov's MediaPlug Slave interface has been incorporated into the S1D13506. The MediaPlug Slave follows the Specification For Winnov MediaPlug Slave, Local module, Document Rev 0.3 with the following exceptions.

17.1 Revision Code

The MediaPlug Slave Revision Code can be determined by reading bits 11:8 of the LCMD register. The revision code for this implementation is 0011b.

17.2 How to enable the MediaPlug Slave

The MediaPlug Slave interface uses the upper eight pins of the LCD data bus (FPDAT[15:8]) for the data bus, clock, and control lines. When pin MD13 is high at the rising edge of RESET#, FPDAT[15:8] are dedicated to the MediaPlug interface.

Table 17-1: MediaPlug Interface Pin Mapping

<table>
<thead>
<tr>
<th>S1D13506 Pin Names</th>

</tr>
<tr>
<td>FPDAT15</td>
<td>O</td>
<td>VMPCLKN</td>
</tr>
<tr>
<td>DRDY or MA11</td>
<td>O</td>
<td>VMPEPWR</td>
</tr>
</tbody>
</table>

Note

If MediaPlug is enabled, any 16-bit LCD panel must use an external circuit to support FPDAT[15:8].

Either pin MA11 or pin DRDY can be configured as the MediaPlug power control output, VMPEPWR. This is selected by the states of MD14, MD7, MD6 at the rising edge of RESET# - see Table 5-6; “Summary of Power-On/Reset Options,” on page 39.

VMPEPWR is controlled by bit 1 of the MediaPlug LCMD register.
18 Clocking

18.1 Frame Rate Calculation

18.1.1 LCD Frame Rate Calculation

The maximum LCD frame rate is calculated using the following formula.

\[
\text{max. LCD Frame Rate} = \frac{\text{LCD PCLK}_{max}}{\left(\text{LHDP} + \text{LHNDP}\right) \times \left(\frac{\text{LVDP}}{n} + \text{LVNDP}\right)}
\]

Where:

- \(\text{LCD PCLK}_{max}\) = maximum LCD pixel clock frequency
- \(\text{LVDP}\) = LCD Vertical Display Height
  \[\text{LVDP} = (\text{REG}[039h] \text{ bits}[1:0], \text{REG}[038h] \text{ bits}[7:0]) + 1\]
- \(\text{LVNDP}\) = LCD Vertical Non-Display Period
  \[\text{LVNDP} = \text{REG}[03Ah] \text{ bits}[5:0] + 1\]
- \(\text{LHDP}\) = LCD Horizontal Display Width
  \[\text{LHDP} = (\text{REG}[032h] \text{ bits}[6:0] + 1) \times 8\text{Ts}\]
- \(\text{LHNDP}\) = LCD Horizontal Non-Display Period
  \[\text{LHNDP} = (\text{REG}[034h] \text{ bits}[4:0] + 1) \times 8\text{Ts}\]
- \(\text{Ts}\) = minimum LCD pixel clock (LPCLK) period
- \(n\) = 1 for single panel
  = 2 for dual panel
18.1.2 CRT Frame Rate Calculation

The maximum CRT frame rate is calculated using the following formula.

\[
\text{max. CRT Frame Rate} = \frac{\text{CRT PCLK}_{\text{max}}}{(\text{CHDP} + \text{CHNDP}) \times (\text{CVDP} + \text{CVNDP})}
\]

Where:

CRT PCLK\(_{\text{max}}\) = maximum CRT pixel clock frequency

CVDP = CRT Vertical Display Height
\[= (\text{REG}[057h] \text{ bits [1:0]}, \text{REG}[056h] \text{ bits [7:0]]) + 1\]

CVNDP = CRT Vertical Non-Display Period
\[= \text{REG}[058h] \text{ bits [6:0]} + 1\]

CHDP = CRT Horizontal Display Width
\[= (\text{REG}[050h] \text{ bits [6:0]} + 1) \times 8\text{Ts}\]

CHNDP = CRT Horizontal Non-Display Period
\[= (\text{REG}[052h] \text{ bits [5:0]} + 1) \times 8\text{Ts}\]

Ts = minimum CRT pixel clock (CPCLK) period
18.1.3 TV Frame Rate Calculation

The maximum TV frame rate is calculated using the following formula.

\[
\text{max. TV Frame Rate} = \frac{\text{TV PCLK}_{\text{max}}}{(\text{THDP} + \text{THNDP}) \times (\text{TVDP} + \text{TVNDP} + 0.5)}
\]

Where:

TV PCLK\text{max} = \text{maximum TV pixel clock frequency}

TVDP = TV Vertical Display Height

= \text{(REG}[057h]\text{ bits [1:0], REG}[056h]\text{ bits [7:0])} + 1

TVNDP = TV Vertical Non-Display Period

= \text{REG}[058h]\text{ bits [6:0] + 1}

THDP = TV Horizontal Display Width

= \text{(REG}[050h]\text{ bits [6:0] + 1) x 8Ts}

THNDP = TV Horizontal Non-Display Period

= \text{(REG}[052h]\text{ bits [5:0] x 8Ts) + 6 for NTSC output}

= \text{(REG}[052h]\text{ bits [5:0] x 8Ts) + 7 for PAL output}

Ts = minimum TV pixel clock (TPCLK) period
18.2 Example Frame Rates

For all example frame rates the following conditions apply:

- Dual panel buffer is enabled for dual panel.
- TV flicker filter is enabled for TV.
- MCLK is 40MHz.

18.2.1 Frame Rates for 640x480 with EISD Disabled

= Example Frame Rates with Ink Layer Enabled

The FIFO values for these display modes must be set as follows:
1. REG[04Ah] must be set to 1Ah.
2. REG[04Ah] must be set to Fh.
3. REG[04Ah], REG[06Ah] must be set to 30h. REG[04Bh], REG[06Bh] must be set to 32h.

= Example Frame Rates with Ink Layer Enabled
19  Power Save Mode

The S1D13506 has been designed for very low-power applications. During normal operation, internal clock networks are dynamically disabled when not required. Similarly, the LCD and/or CRT/TV pipelines are shut down when not required in the selected display mode. Additionally, the S1D13506 has a software initiated power save mode.

19.1  Display Modes

The S1D13506 resets with both displays inactive, i.e. neither the LCD nor CRT/TV pipelines are active. The displays are independently enabled/disabled by REG[1FCh] bits 2-0: the CRT/TV is instantaneously enabled/disabled by these bits; the LCD is powered up/down according to the sequences in Section 7.4, “Power Sequencing” on page 78.

19.2  Power Save Mode

Power save mode is invoked by setting REG[1F0h] bit 0 to 1. In power save mode, both displays are disabled: the CRT/TV is instantaneously disabled; the LCD is powered down according to the sequences in Section 7.4, “Power Sequencing” on page 78. Access to memory is not allowed and the memory controller merely refreshes the memory in the method selected by REG[021h]. Register access is allowed.

19.3  Power Save Status Bits

**LCD Power Save Status bit**

The LCD Power Save Status bit (REG[1F1h] bit 0), when 1, indicates that the panel is powered down. When this bit is 0, the panel is powered up, or in transition of powering up or down. The system may disable the LCD pixel clock source when this bit is 1. This bit is 1 after chip reset.

**Memory Controller Power Save Status bit**

The Memory Controller Power Save Status bit (REG[1F1h] bit 1, when 1, indicates that the DRAM interface is powered down - the DRAM is either in self-refresh mode or completely idle. This condition occurs shortly after power save mode is invoked, provided Self-Refresh or No Refresh is pre-selected (see REG[021h] bits 7-6); this condition will never occur if CBR Refresh is selected. When this bit is 0, the DRAM interface is active. The system may disable the memory clock source when this bit is 1. This bit is 0 after chip reset.
19.4 Power Save Mode Summary

Note
1. LCD pixel clock required.
2. CRT/TV pixel clock required.
3. Selectable; may observe CBR refresh, self-refresh or no refresh at all.
20 Clocks

20.1 Clock Selection

The following diagram provides a logical representation of the S1D13506 internal clocks.

![Clock Selection Diagram](image-url)

*Figure 20-1: Clock Selection*
20.2 Clock Descriptions

20.2.1 MCLK

MCLK should be configured as close to its maximum (40MHz) as possible. The S1D13506 contains sophisticated clock management, therefore, very little power is saved by reducing the MCLK frequency.

The frequency of MCLK is directly proportional to the bandwidth of the video memory. The bandwidth available to the CPU (for screen updates) is that left over after screen refresh takes its share. CPU bandwidth can be seriously reduced when the MCLK frequency is reduced, especially for high-resolution, high-color modes where screen refresh has high bandwidth requirements.

20.2.2 LCD PCLK

LCD PCLK should be chosen to match the optimum frame rate of the panel. See Section 18, “Clocking” on page 212 for details on the relationship between PCLK and frame rate, and for the maximum supportable PCLK frequencies for any given video mode.

Some flexibility is possible in the selection of PCLK. Panels typically have a range of permissible frame rates making it possible to choose a higher PCLK frequency and adjust the horizontal non-display period (see REG[052h]) to bring the frame-rate down to its optimal value.

20.2.3 CRT/TV PCLK

TVs and older CRTs usually have very precise frequency requirements, so it may be necessary to dedicate one of the clock inputs to this function. More recent CRTs work within a range of frequencies, so it may be possible to support them with BUSCLK or MCLK.

TV mode with flicker filter requires PCLK to be twice (2x) the standard NTSC (14.xxxMHz) and PAL (17.xxxMHz) clocks. A clock multiplier is used to create this clock, REG[018h] bit 7 is used to enable it. Note that the clock 2x clock could also be used for CRT support.

20.2.4 MediaPlug Clock

The MediaPlug Clock must be twice (2x) the frequency of VMPCLK. For timing see Section 7.7, “MediaPlug Interface Timing” on page 123. VMPCLK is typically in the range 6-8MHz so MediaPlug Clock must be in the range of 12-16MHz.
20.3 Clocks vs. Functions

The S1D13506 has five clock signals. Not all clock signals must be active for certain chip functions to be carried out. The following table shows which clocks are required for each chip function.

*Table 20-1: Clocks vs. Functions*

1 Introduction

This guide provides information on programming the S1D13506 Color LCD/CRT/TV Controller. Included are algorithms which demonstrate how to program the S1D13506. This guide discusses Power-on Initialization, Panning and Scrolling, LUT initialization, LCD Power Sequencing, SwivelView™, etc. The example source code referenced in this guide is available on the web at www.eea.epson.com.

This guide also introduces the Hardware Abstraction Layer (HAL), which is designed to simplify the programming of the S1D13506. Most S1D1350x and S1D1370x products have HAL support, thus allowing OEMs to do multiple designs with a common code base.

This document will be updated as appropriate. Please check the Epson Electronics America Website at www.eea.epson.com for the latest revision of this document and source before beginning any development.

We appreciate your comments on our documentation. Please contact us via email at techpubs@erd.epson.com.
2 Initialization

This section describes how to initialize the S1D13506. Sample code for performing initialization of the S1D13506 is provided in the file `init13506.c` which is available on the internet at www.eea.epson.com.

S1D13506 initialization can be broken into three steps.

- Enable the S1D13506 controller (if necessary identify the specific controller).
- Set all the registers to their initial values.
- Program the Look-Up Table (LUT) with color values. This section does not deal with programming the LUT, for details see Section 4, “Look-Up Table (LUT)”.

The simplest way to generate initialization tables for the S1D13506 is to use the utility program 13506CFG.EXE which to generates a header file that can be used by Windows CE or the HAL. Otherwise modify the `init13506.c` file directly.

The following table represents the sequence and values written to the S1D13506 registers to control a configuration with these specifications:

- 640x480 color format 1 dual passive LCD @ 78Hz.
- 16-bit data interface.
- 8 bit-per-pixel (bpp) color depth - 256 colors.
- 40 MHz input clock CLKI.
- CLKI used for BUSCLK (1:1); PCLK (2:1); MCLK (1:1).
- 50 ns EDO-DRAM, 2 CAS, 32 ms refresh.

3 Memory Models

The S1D13506 is capable of several color depths. The memory model for each color depth is packed pixel. The S1D13506 supports 4, 8, 15 and 16 bit-per-pixel (bpp) memory models.

3.1 Display Buffer Location

The S1D13506 supports either a 512k byte or 2M byte display buffer. The display buffer is memory mapped and is accessible directly by software. The memory block location assigned to the S1D13506 display buffer varies with each individual hardware platform.

For further information on the display buffer, see the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx.

3.2 Memory Organization for 4 Bpp (16 Colors/16 Gray Shades)

<td>Pixel 1</td>
<td>Bits 3-0</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*Figure 3-1: Pixel Storage for 4 Bpp in One Byte of Display Buffer*

In this memory format each byte of display buffer contains two adjacent pixels. Setting or resetting any pixel will require reading the entire byte, masking out the upper or lower nibble (4 bits) and setting the appropriate bits to 1.

Four bit pixels provide 16 gray shades/color possibilities. For monochrome panels the gray shades are generated by indexing into the first 16 elements of the green component of the Look-Up Table (LUT). For color panels the 16 colors are derived by indexing into the first 16 positions of the LUT.
3.3 Memory Organization for 8 Bpp (256 Colors/16 Gray Shades)

At a color depth of eight bpp each byte of display buffer represents one pixel on the display. At this color depth the read-modify-write cycles of 4 bpp are eliminated making the update of each pixel faster.

Each byte indexes into one of the 256 positions of the LUT. The S1D13506 LUT supports four bits per primary color. This translates into 4096 possible colors when color mode is selected. Therefore the displayed mode has 256 colors available out of a possible 4096.

When a monochrome panel is selected, the green component of the LUT is used to determine the gray shade intensity. The green indices, with only four bits, can resolve 16 gray shades.

**Note**
When a monochrome panel (REG[030h] bit 2 = 0) is selected, a four bpp color depth also provides 16 gray shades and uses less display buffer.

3.4 Memory Organization for 15 Bpp (32768 Colors/32 Gray Shades)

At a color depth of 15 bpp the S1D13506 is capable of displaying 32768 colors. The 32768 color pixel is divided into four parts: one reserved bit, five bits for red, five bits for green, and five bits for blue. In this mode the LUT is bypassed and output goes directly into the Frame Rate Modulator.
When dithering is enabled (REG[041h] bit 1) the full color range is available on all display types. If dithering is disabled the full color range is only available on TFT/D-TFD or CRT displays. Passive LCD displays are limited to using the four most significant bits from each of the red, green and blue portions of each color resulting in 4096 \((2^4 \times 2^4 \times 2^4)\) possible colors.

Should a monochrome panel be used at this color depth, the output sends the five bits of the green LUT component to the modulator for a total of 32 possible gray shades. If dithering is disabled, the maximum number of gray shades is 16.

### 3.5 Memory Organization for 16 Bpp (65536 Colors/64 Gray Shades)

</tr>
</tbody>
</table>

*Figure 3-4: Pixel Storage for 16 Bpp in Two Bytes of Display Buffer*

At a color depth of 16 bpp the S1D13506 is capable of displaying 65536 colors. The 65536 color pixel is divided into three parts: five bits for red, six bits for green, and five bits for blue. In this mode the LUT is bypassed and output goes directly into the Frame Rate Modulator.

When dithering is enabled (REG[041h] bit 1) the full color range is available on all display types. If dithering is disabled the full color range is only available on TFT/D-TFD or CRT displays. Passive LCD displays are limited to using the four most significant bits from each of the red, green and blue portions of each color resulting in 4096 \((2^4 \times 2^4 \times 2^4)\) possible colors.

Should monochrome mode be chosen at this color depth, the output sends the six bits of the green LUT component to the modulator for a total of 64 possible gray shades. If dithering is disabled, the maximum number of gray shades is 16.
4 Look-Up Table (LUT)

This section discusses programming the S1D13506 Look-Up Table (LUT). Included is a summary of the LUT registers, recommendations for color/gray shade LUT values, and additional programming considerations. For a discussion of the LUT architecture, refer to the *S1D13506 Hardware Functional Specification*, document number X25B-A-001-xx.

The S1D13506 is designed with a separate LUT for both the LCD and CRT/TV. Each LUT consists of 256 indexed red/green/blue entries. Each LUT entry is four bits wide. The color depth determines how many indices are used to output the image to the display. 4 bpp uses the first 16 indices, 8 bpp uses all 256 indices, and 15/16 bpp color depths bypass the LUT entirely.

In color modes, the pixel values stored in the display buffer index directly to an RGB value stored in the LUT. In monochrome modes, the pixel value indexes into the green component of the LUT and the amount of green at that index controls the intensity. Monochrome mode look-ups are done based on the Color/Mono Panel Select bit (REG[030h] bit 2). The CRT interface receives the RGB values from the LUT even if simultaneous display is used with a monochrome panel. Therefore, it is important to program the R, G, and B components of the CRT LUT either with a unique set of values, or with R, G, and B values all equivalent.

4.1 Registers

### REG[1E0h] Look-Up Table Mode Register

<table>
<thead>
<tr>
<th>LUT Mode Bit 1</th>
<th>LUT Mode Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
<td>n/a</td>
</tr>
<tr>
<td>n/a</td>
<td>n/a</td>
</tr>
<tr>
<td>n/a</td>
<td>n/a</td>
</tr>
<tr>
<td>n/a</td>
<td>n/a</td>
</tr>
<tr>
<td>LUT Mode Bit 1</td>
<td>LUT Mode Bit 0</td>
</tr>
</tbody>
</table>

The S1D13506 is designed with a separate LUT for both the LCD and CRT/TV. The LUT Mode register selects which of the LUTs will be accessed by the CPU when reads/writes are made to REG[1E2h] and REG[1E4h]. LUT mode selection allows the LUTs to be individually written or have identical data written to both LUTs. Individual writes to these registers are useful for Epson Independent Simultaneous Display (EISD) modes where independent images are displayed on the LCD and the CRT/TV. For further information on Epson Independent Simultaneous Display, see the *S1D13506 Hardware Functional Specification*, document number X25B-A-001-xx.

For normal operation, this register should be set to 00h which will read the LCD LUT and write both the LCD and CRT/TV LUTs with identical data. For selection of other LUT modes, see REG[1E0h] in the *S1D13506 Hardware Functional Specification*, document number X25B-A-001-xx.

### REG[1E2h] Look-Up Table Address Register

<table>
<thead>
<tr>
<th>LUT Address Bit 7</th>
<th>LUT Address Bit 6</th>
<th>LUT Address Bit 5</th>
<th>LUT Address Bit 4</th>
<th>LUT Address Bit 3</th>
<th>LUT Address Bit 2</th>
<th>LUT Address Bit 1</th>
<th>LUT Address Bit 0</th>
</tr>
</thead>
</table>

The LUT address register selects which of the 256 LUT entries will be accessed. Writing to this register will select the red bank. After three successive reads or writes to the data register (REG[1E4h]) this register is automatically incremented by one.

<table>
<thead>
<tr>
<th>LUT Data Bit 3</th>
<th>LUT Data Bit 2</th>
<th>LUT Data Bit 1</th>
<th>LUT Data Bit 0</th>
<th>n/a</th>
<th>n/a</th>
<th>n/a</th>
<th>n/a</th>
</tr>
</thead>
</table>

This register is where the 4-bit red/green/blue data is written to/read from. With each successive read or write the internal bank select is incremented. Three successive reads from this register will result in reading the red, then the green, and finally the blue values associated with the index set in the LUT address register.

After the third read the LUT address register is incremented and the internal bank select points to the red bank again.

### 4.2 Look-Up Table Organization

- The Look-Up Table treats the value of a pixel as an index into an array of colors or gray shades. For example, a pixel value of zero would point to the first LUT entry, whereas a pixel value of seven would point to the eighth LUT entry.
- The value contained in each LUT entry represents the intensity of the given color or gray shade. This intensity can range in value between 0 and 0Fh.
- The S1D13506 Look-Up Table is linear. This means increasing the LUT entry number results in a lighter color or gray shade. For example, a LUT entry of 0Fh in the red bank results in bright red output while a LUT entry of 05h results in dull red.

4.2.1 Color Modes

In color display modes, the number of LUT entries used is automatically selected depending on the color depth.

4 bpp color

When the S1D13506 is configured for 4 bpp color mode the first 16 entries in the LUT are used. Each byte in the display buffer contains two adjacent pixels. The upper and lower nibbles of the byte are used as indices into the LUT.

The following table shows LUT values that will simulate those of a VGA operating in 16 color mode.

</tbody>
</table>

= Indicates unused entries in the LUT
8 bpp color

When the S1D13506 is configured for 8 bpp color mode all 256 entries in the LUT are used. Each byte in the display buffer corresponds to one pixel and is used as an index value into the LUT.

The S1D13506 LUT has four bits (16 intensities) of intensity control per primary color while a standard VGA RAMDAC has six bits (64 intensities). This four to one difference must be considered when attempting to match colors between a VGA RAMDAC and the S1D13506 LUT. (i.e. VGA levels 0 - 3 map to LUT level 0, VGA levels 4 - 7 map to LUT level 1...). Additionally, the significant bits of the color tables are located at different offsets within their respective bytes. After calculating the equivalent intensity value the result must be shifted into the correct bit positions.

The following table shows LUT values that will approximate the VGA default color palette.

| Table 4-3: Suggested LUT Values to Simulate VGA Default 256 Color Palette |

The Look-Up Table is bypassed at this color depth, hence programming the LUT is not required.

### 15 bpp color

The Look-Up Table is bypassed at this color depth, hence programming the LUT is not required.

### 16 bpp color

The Look-Up Table is bypassed at this color depth, hence programming the LUT is not required.
4.2.2 Gray Shade Modes

This discussion of gray shade (monochrome) modes only applies to the panel interface. Monochrome mode is selected when REG[030h] bit 2 returns a 0. In this mode the value output to the panel is derived solely from the green component of the LUT. The CRT/TV image is formed from all three LUT components (RGB).

**Note**
In order to match the colors on a CRT/TV with the colors on a monochrome panel when displaying identical images on the panel and CRT/TV, the red and blue components of the LUT must be set to the same intensity as the green component.

### 4 bpp gray shade

The 4 bpp gray shade mode uses the green component of the first 16 LUT entries. The remaining indices of the LUT are unused.

*Required to match CRT to panel*

*Unused entries*
8 bpp gray shade

The 8 bpp gray shade mode uses the green component of the first 16 LUT entries. The green portion of the LUT provides 16 possible intensities. There is no increase in gray shades when selecting 8 bpp mode over 4 bpp mode; however, Swivelview and the BitBLT engine can be used in 8 bpp mode but not in 4 bpp mode.

15 bpp gray shade

The Look-Up Table is bypassed at this color depth, hence programming the LUT is not required.

As with 8 bpp there are limitations to the colors which can be displayed. In this mode the five bits of green are used to set the absolute intensity of the image. This results in 32 gray shades when dithering is enabled and 16 gray shades when dithering is disabled.

16 bpp gray shade

The Look-Up Table is bypassed at this color depth, hence programming the LUT is not required.

As with 8 bpp there are limitations to the colors which can be displayed. In this mode the six bits of green are used to set the absolute intensity of the image. This results in 64 gray shades when dithering is enabled and 16 gray shades when dithering is disabled.
5 Virtual Displays

This section discusses the concept of a virtual display and covers navigation within a virtual display using panning and scrolling.

5.1 Virtual Display

Virtual display is where the image to be viewed is larger than the physical display. This can be in the horizontal, vertical or both dimensions. To view the image, the display is used as a window (or viewport) into the display buffer. At any given time only a portion of the image is visible. Panning and scrolling are used to view the full image. For further information on panning and scrolling, see Section 5.2, “Panning and Scrolling” on page 30.

The Memory Address Offset registers determine the number of horizontal pixels in the virtual image. The offset registers can be set for a maximum of 2^{11} or 2048 words. At a color depth of 4 bpp, 2048 words cover 8,192 pixels. At a color depth of 16 bpp, 2048 words cover 2048 pixels.

The maximum number of lines of the virtual image is the size of the display buffer divided by the number of bytes per horizontal line. The number of bytes per line equals the number of words in the offset register multiplied by two. At the maximum horizontal size, the greatest number of lines that can be displayed using 2M bytes of display memory is 512. Reducing the horizontal size makes more display buffer available, thus increasing the available virtual vertical size.

In addition to the calculated limit, the virtual vertical size is limited by the size and location of the Dual Panel Buffer and the Ink Layer/Hardware Cursor (if present).

The maximum horizontal/vertical sizes are seldom used. Figure 5-1: “Viewport Inside a Virtual Display,” shows a more typical use of a virtual display. With a display panel of 320x240 pixels, an image of 640x480 pixels can be viewed by navigating a 320x240 pixel viewport around the image using panning and scrolling.

![Figure 5-1: Viewport Inside a Virtual Display](image-url)
5.1.1 Registers

These registers form the 11-bit memory address offset for the LCD display. This offset equals the number of words from the beginning of one line of the LCD display to the beginning of the next line.

To maintain a constant virtual width as color depth changes, the memory address offset must also change. At a color depth of 4 bpp each word contains 4 pixels, at 16 bpp each word contains one pixel. The formula to determine the value for the memory address registers is:

\[
\text{Offset} = \frac{\text{PixelsPerVirtualLine}}{\text{PixelsPerWord}}
\]

This value may not necessarily represent the number of words shown on the LCD display. This is the virtual width of the display image and may be greater than or equal to the physical display width. If PixelsPerVirtualLine equals the physical display width as set in the LCD Horizontal Display Width register (REG[032h]), then the virtual display and physical display are the same size.

These registers form the 11-bit memory address offset for the CRT/TV display. This offset equals the number of words form the beginning of one line of the CRT/TV display to the beginning of the next line.

To maintain a constant virtual width as color depth changes, the memory address offset must also change. At a color depth of 4 bpp each word contains 4 pixels, at 16 bpp each word contains one pixel. The formula to determine the value for the memory address registers is:
Offset = PixelsPerVirtualLine ÷ PixelsPerWord

This value may not necessarily represent the number of words shown on the CRT/TV display. This is the virtual width of the display image and may be greater than or equal to the physical display width. If PixelsPerVirtualLine equals the physical display width as set in the CRT/TV Horizontal Display Width register (REG[050h]), then the virtual display and physical display are the same size.

5.1.2 Examples

Example 1: Determine the offset value required for a line of 800 pixels at a color depth of 8 bpp.

At a color depth of 8 bpp each byte contains one pixel, therefore each word contains two pixels.

\[
\text{PixelsPerWord} = \frac{16}{\text{bpp}} = \frac{16}{8} = 2
\]

To calculate the offset value for this example, the following formula is used.

\[
\text{Offset} = \frac{\text{PixelsPerVirtualLine}}{\text{PixelsPerWord}} = \frac{800}{2} = 400 = 190h \text{ words}
\]

For the LCD, REG[047h] is set to 01h and REG[046h] is set to 90h. For the CRT/TV, REG[067h] is set to 01h and REG[066h] is set to 90h.

Example 2: Program the Memory Address Offset Registers to support a 16 color (4 bpp) 800x600 virtual display on a 640x480 LCD panel.

To create a virtual display the offset registers must be programmed to the horizontal size of the larger “virtual” image. After determining the amount of memory used by each line (see example 1), calculate whether there is enough memory to support the desired number of lines.

1. Initialize the S1D13506 registers for a 640x480 panel. (See Section 2, “Initialization” on page 12).

2. Calculate the number of pixels per word.

\[
\text{PixelsPerWord} = \frac{16}{\text{bpp}} = \frac{16}{4} = 4
\]

3. Determine the offset register value.
Offset = PixelsPerVirtualLine ÷ PixelsPerWord
= 800 ÷ 4
= 200 words
= 0C8h words

For the LCD, REG[047h] is set to 00h and REG[046h] is set to C8h.
For the CRT/TV, REG[067h] is set to 00h and REG[066h] is set to C8h.

4. To confirm whether there is enough memory for the required virtual height, the following formula is used.

MemoryRequired = WordsPerVirtualLine x 2 x NumberofLines
= 200 x 2 x 600
= 240,000 bytes

This display configuration is supported on a system with the minimum supported memory size of 512K bytes. It is safe to continue with these values.
5.2 Panning and Scrolling

The terms panning and scrolling refer to the actions used to move a viewport about a virtual display. Although the entire image is stored in the display buffer, only a portion is visible at any given time.

Panning describes the horizontal (side to side) motion of the viewport. When panning to the right the image in the viewport appears to slide to the left. When panning to the left the image to appears to slide to the right. Scrolling describes the vertical (up and down) motion of the viewport. Scrolling down causes the image to appear to slide up and scrolling up causes the image to appear to slide down.

Both panning and scrolling are performed by modifying the start address registers. The start address refers to the word offset in the display buffer where the beginning of the image is displayed from. At color depths less than 15 bpp, another register is required for smooth movement. The pixel pan registers (REG[048h] for LCD, REG[068h] for CRT/TV) allow panning in smaller increments than changing the start address alone.

Internally, the S1D13506 latches different signals at different times. Due to this internal sequence, the start address and pixel pan registers should be accessed in a specific order during panning and scrolling operations, in order to provide the smoothest scrolling. Setting the registers in the wrong sequence, or at the wrong time, results in a “tearing” or jitter effect on the display.

The start address is latched at the beginning of each frame, so the start address can be set within the vertical non-display period (VNDP). The pixel pan register values are latched at the beginning of each display line and must be set during the vertical non-display period. The correct sequence for programing these registers is:

1. Wait for the beginning of the vertical non-display period - For the LCD, REG[03Ah] bit 7 will return a 1 during VNDP; for the CRT/TV, REG[058h] bit 7 will return a 1 during VNDP. Wait for the transition of the appropriate bit to go from 0 to 1. This ensures the register updates are carried out at the beginning of VNDP.

2. Update the start address registers - For the LCD, REG[042h], REG[043h], REG[044h]; for the CRT/TV, REG[062h], REG[063h], REG[064h].

3. Update the pixel panning register - For the LCD, REG[048h] bits 1-0; for the CRT/TV REG[068h] bits 1-0.

Sample code for panning and scrolling is available in the file hal_virt.c which is included in the HAL source code available on the internet at www.eea.epson.com.
5.2.1 Registers

The Display Start Address registers form the word address to the display buffer where the LCD or CRT/TV starts displaying from. An address of 0 points to the beginning of the display buffer. Changing the start address registers by one pans from 1 to 4 pixels depending on the current color depth. The following table lists the maximum number of pixels affected by a change of one to these registers.

### Table 5-1: Number of Pixels Panned When Start Address Changed By 1

<table>
<thead>
<tr>
<th>Color Depth (bpp)</th>
<th>Pixels per Word</th>
<th>Number of Pixels Panned</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>8</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>15</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>16</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
The pixel panning register offers finer control over panning than is available using the start address registers. Using the pixel panning register, it is possible to pan the displayed image one pixel at a time. The number of bits required to pan a single pixel at a time, change with the color depth. The following table shows the bits of the pixel pan register which are used for each color depth.

### Table 5-2: Active Pixel Pan Bits

<table>
<thead>
<tr>
<th>Color Depth (bpp)</th>
<th>Pixel Pan bits used</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>bits [1:0]</td>
</tr>
<tr>
<td>8</td>
<td>bit 0</td>
</tr>
<tr>
<td>15/16</td>
<td>none</td>
</tr>
</tbody>
</table>

**Note**
The pixel panning registers are not required for color depths of 15 or 16 bpp.

The pixel panning registers must be updated in conjunction with the start address registers. The pixel panning registers can be thought of as the least significant bit(s) of the start address registers.

When panning to the right on an LCD set for a color depth of 4 bpp, the registers would be updated as follows.

1. Pan right by 1 pixel - increment the pixel panning register by 1: REG[048h] = 01b.
2. Pan right by 1 pixel - increment the pixel panning register by 1: REG[048h] = 10b.
4. Pan right by 1 pixel - reset the pixel panning register to 0: REG[048h] = 00b.
   - increment the start address register by 1: (REG[042h], REG[043h], REG[044h]) + 1.

**Note**
The above example assumes the pixel panning register is initially set at 0.
When panning to the left on an LCD set for a color depth of 4 bpp, the registers would be updated as follows.

1. Pan left by 1 pixel - decrement the pixel panning register by 1: REG[048h] = 11b.  
   - decrement the start address register by 1: (REG[042h], REG[043h], REG[044h]) - 1.

2. Pan left by 1 pixel - decrement the pixel panning register by 1: REG[048h] = 10b.

3. Pan left by 1 pixel - decrement the pixel panning register by 1: REG[048h] = 01b.

4. Pan left by 1 pixel - decrement the pixel panning register by 1: REG[048h] = 00b.

**Note**

The above example assumes the pixel panning register is initially set at 0.

### 5.2.2 Examples

The following examples assume the display system has been configured to view a 800x600 pixel image in a 640x480 viewport. Refer to Section 2, “Initialization” on page 12 and Section 5.1, “Virtual Display” on page 26 for assistance with these settings.

**Example 3: Panning - Right and Left**

To pan to the right, increment the value in the pixel panning register (REG[048h] for LCD, REG[068h] for CRT/TV). When the pixel pan value reaches the maximum value for the current color depth (i.e. 11b for 4 bpp, 1b for 8 bpp) then set the pixel pan value to zero and increment the start address value. To pan to the left (assuming the pixel panning register is zero), decrement the value in the pixel panning register and decrement the start address register. When the pixel pan value reaches zero then decrement both the pixel panning register and start address register again. If the pixel panning register contains a value other than zero, decrement the value in the pixel panning register only and when the pixel pan value reaches zero, decrement both the pixel panning register and start address register.

**Note**

Panning operations are easier to follow if a variable (e.g. PanValue) is used to track both the pixel panning and start address registers. The least significant bits of PanValue will represent the pixel panning register value and the more significant bits are the start address register value.

The following example pans to the right by one pixel when the color depth is 4 bpp.

1. Increment PanValue.
   
   \[
   \text{PanValue} = \text{PanValue} + 1
   \]

2. Mask off the values from PanValue for the pixel panning and start address register portions. In this case, 4 bpp, the lower two bits are the pixel panning value and the upper bits are the start address.
   
   \[
   \text{PixelPan} = \text{PanValue} \text{ AND } 3
   \]
StartAddress = PanValue SHR 2 (remove PixelPan bits)

3. Write the pixel panning and start address register values using the procedure outlined in Section 5.2.1, “Registers” on page 31.

**Example 4: Scrolling - Up and Down**

To scroll down, increase the value in the Display Start Address Registers (REG[042h], REG[043h], REG[044h] for LCD, REG[062h], REG[063h], REG[064h] for CRT/TV) by the number of words in one *virtual* scan line. To scroll up, decrease the value in the Display Start Address Registers by the number of words in one *virtual* scan line.

The following example scrolls down one line for a 16 color (4 bpp) 800x600 virtual image using a 640x480 single panel LCD.

1. Determine the number of words in each line of the virtual image. For a color depth of 4 bpp each byte contains two pixels so each word contains 4 pixels.
   
   $$\text{OffsetWords} = \text{PixelsPerVirtualLine} \div \text{PixelsPerWord} = 800 \div 4 = 200 = \text{C8h}$$

2. Increment the display start address by the number of words per virtual line.
   
   $$\text{StartAddress} = \text{StartAddress} + \text{OffsetWords} = \text{StartAddress} + \text{C8h}$$

3. Separate the display start address value into three bytes. For the LCD, write the LSB to REG[042h] and the MSB to REG[044h]. For the CRT/TV, write the LSB to REG[062h] and the MSB to REG[064h].

   For the LCD, REG[044h] is set to 00h, REG[043h] is set to 00h, and REG[042h] is set to C8h.

   For the CRT/TV, REG[064h] is set to 00h, REG[063h] is set to 00h, and REG[062h] is set to C8h.

**Note**

The above example assumes the display start address was initially 0 (the beginning of the display buffer).
6  Power Save Mode

The S1D13506 has been designed for very low-power applications. During normal operation, the internal clocks are dynamically disabled when not required. The S1D13506 design also includes a Power Save Mode to further save power. When Power Save Mode is initiated, automatic LCD power sequencing takes place to ensure the LCD bias power supply is disabled properly. For further information on LCD power sequencing, see Section 7, “LCD Power Sequencing” on page 38.

6.1  Overview

The S1D13506 supports a software initiated Power Save Mode. Enabling/disabling Power Save Mode is controlled using the Power Save Mode Enable bit (REG[1F0h] bit 0). The type of DRAM refresh used during Power Save Mode can also be selected by software.

While Power Save Mode is enabled the following conditions apply.

- Display(s) are inactive.
- Registers are accessible.
- Memory is in-accessible.
- LUT is accessible.

6.2  Registers

6.2.1  Enabling Power Save Mode

<table>
<thead>
<tr>
<th>REG[1F0h] Power Save Configuration Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
</tr>
</tbody>
</table>

The Power Save Mode Enable bit initiates Power Save Mode when set to 1. Setting the bit back to 0 returns the S1D13506 back to normal mode.
### 6.2.2 Power Save Status Bits

<table>
<thead>
<tr>
<th>REG[1F1h] Power Save Status Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
</tr>
</tbody>
</table>

The LCD Power Save Status bit is a read-only status bit which indicates the power save state of the LCD panel. When this bit returns a 1, the panel is powered-off. When this bit returns a 0, the LCD panel is powered up or in transition of powering up or down. This bit will return a 1 after a chip reset.

**Note**

The LCD pixel clock source may be disabled when this bit returns a 1.

<table>
<thead>
<tr>
<th>REG[1F1h] Power Save Status Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
</tr>
</tbody>
</table>

The Memory Controller Power Save Status bit is a read-only status bit which indicates the power save state of the S1D13506 DRAM interface. When this bit returns a 1, the DRAM interface is powered down (the DRAM is either in self-refresh mode or completely idle). When this bit returns a 0, the DRAM interface is active. This bit will return a 0 after a chip reset.

For this bit to return a 1, the DRAM Refresh Select bits must select either self-refresh or no refresh. For information on the DRAM Refresh Select bits, see Section 6.2.3, “DRAM Refresh Selection” on page 37.

**Note**

The memory clock source may be disabled when this bit returns a 1.
6.2.3 DRAM Refresh Selection

<table>
<thead>
<tr>
<th>REG[021h] DRAM Refresh Rate Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>Refresh Select Bit 1</td>
</tr>
<tr>
<td>Refresh Select Bit 0</td>
</tr>
<tr>
<td>n/a</td>
</tr>
<tr>
<td>n/a</td>
</tr>
<tr>
<td>n/a</td>
</tr>
<tr>
<td>DRAM Refresh Rate Bit 2</td>
</tr>
<tr>
<td>DRAM Refresh Rate Bit 1</td>
</tr>
<tr>
<td>DRAM Refresh Rate Bit 0</td>
</tr>
</tbody>
</table>

The Refresh Select bits specify the type of DRAM refresh used while Power Save Mode is enabled. DRAM refresh selection is as follows.

**Table 6-1: Refresh Selection**

<table>
<thead>
<tr>
<th>Refresh Select Bits [1:0]</th>
<th>DRAM Refresh Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>CAS-before-RAS (CBR) refresh</td>
</tr>
<tr>
<td>01</td>
<td>Self-Refresh</td>
</tr>
<tr>
<td>1X</td>
<td>No Refresh</td>
</tr>
</tbody>
</table>

The Refresh Select bits must be set before Power Save Mode is enabled. While CBR refresh is selected the memory controller cannot be powered down and the memory clock source must remain active. If either self-refresh or no refresh is selected the memory controller may be powered down and the memory clock source may be disabled. For further information, see Section 6.2.2, “Power Save Status Bits” on page 36.

**Note**

The Refresh Select bits must not be changed while in power save mode.
7 LCD Power Sequencing

The S1D13506 is designed with internal circuitry which automates LCD power sequencing (the process of powering-on and powering-off the LCD panel). LCD power sequencing allows the LCD bias voltage to discharge prior to shutting down the LCD signals, preventing long term damage to the panel and avoiding unsightly “lines” at power-on/power-off.

Proper LCD power sequencing for power-off requires a delay from the time the LCD power is disabled to the time the LCD signals are shut down. Power-on requires the LCD signals to be active prior to applying power to the LCD. This time interval varies depending on the LCD bias power supply design. For example, the LCD bias power supply on the S5U13506 Evaluation board requires 0.5 seconds to fully discharge. Other power supply designs may vary.

For most applications automatic power sequencing is the appropriate choice, see Section 7.1, “Automatic Sequencing”. However, there may be situations where the internal time delay is insufficient to discharge the LCD bias power supply before the LCD signals are shut down. For the sequence used to manually power-off the LCD panel, see Section 7.2, “Manual Sequencing”.

7.1 Automatic Sequencing

LCD power sequencing is automatically provided when the S1D13506 is powered-on or powered-off using the built-in Power Save Mode. The Power Save Mode is enabled using REG[1F0h] bit 0. For more information on Power Save Mode, see Section 6, “Power Save Mode”.

For LCD power sequencing AC Timing, see the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx.

7.2 Manual Sequencing

In cases where automatic LCD power sequencing is not applicable, manual sequencing can be done. This section assumes the LCD bias power is controlled through GPIO1. The S1D13506 GPIO pins are multi-use pins and may not be available in all system designs. For further information on the availability of GPIO pins, see the S1D13506 Hardware Functional Specification, document number X25B-B-001-xx.
### 7.2.1 Registers

<table>
<thead>
<tr>
<th>LCD Display Blank</th>
<th>n/a</th>
<th>n/a</th>
<th>SwivelView Enable Bit 1</th>
<th>n/a</th>
<th>LCD Bit-per-pixel Select Bit 2</th>
<th>LCD Bit-per-pixel Select Bit 1</th>
<th>LCD Bit-per-pixel Select Bit 0</th>
</tr>
</thead>
</table>

When set to 1, this bit disables the LCD display pipeline and forces all LCD data outputs to zero. This effectively blanks the screen.

**Note**
If a dual panel is used, the Dual Panel Buffer must be disabled before blanking the LCD display. This is done by setting REG[041h] bit 0 to 1b.

### 7.2.2 Enabling the LCD Panel

If the LCD bias power supply timing requirements are different than those timings built into the S1D13506 automated LCD power sequencing, it may be necessary to manually enable the LCD panel. In such a case, the following procedure applies.

1. Enable the LCD signals - Set REG[040h] = 0.

**Note**
If a dual panel is used, enable the Dual Panel Buffer by setting REG[041h] bit 0 = 0b.

2. Enable GPIO1 to activate the LCD bias power.

### 7.2.3 Disabling the LCD Panel

If the LCD bias power supply timing requirements are different than those timings built into the S1D13506 automated LCD power sequencing, it may be necessary to manually disable the LCD panel. In such a case, the following procedure applies.

1. Disable the LCD power using GPIO1.

2. Wait the required delay time for the LCD bias power supply to discharge.

3. Disable the LCD signals - Set REG[040h] = 1.

4. Disable the LCD pixel clock source if desired. (Optional)
8 Hardware Cursor/Ink Layer

8.1 Introduction

The S1D13506 supports either a Hardware Cursor or an Ink Layer for the LCD, and either a Hardware Cursor or an Ink Layer for the CRT/TV. The LCD and CRT/TV are supported independently, so it is possible to select combinations such as a Hardware Cursor on the LCD and an Ink Layer on the CRT/TV.

A Hardware Cursor improves video throughput in graphical operating systems by off-loading much of the work typically assigned to software. For example, consider the actions which must be performed when the user moves the mouse. On a system without hardware support, the operating system must restore the area under the current cursor position, save the area under the new location, and finally draw the cursor shape. Contrast that with the hardware assisted system where the operating system must simply update the cursor X and cursor Y position registers.

An Ink Layer is designed to support stylus or pen input. Without an ink layer, the operating system must save the area of the display buffer (possibly all) where pen input is to occur. After the system recognizes the characters entered, the display would have to be restored and the characters redrawn in a system font. When an Ink Layer is present, the stylus path is drawn in the Ink Layer where it overlays the displayed image. After character recognition finishes the display is updated with the new characters and the ink layer is simply cleared. Saving and restoring the display data is not required providing faster throughput.

The S1D13506 Hardware Cursor/Ink Layer supports a 2 bpp (four color) overlay image. Two of the available colors are transparent and invert. The remaining two colors are user definable.

The Hardware Cursor uses many of the same registers as the Ink Layer. Additionally, the cursor has positional registers for movement. The cursor resolution is 64x64 at a color depth of 2 bpp. The Ink Layer resolution is the width of the display by the height of the display at a color depth of 2 bpp. Both the Hardware Cursor and the Ink Layer use the same pixel values to select colors. The Hardware Cursor requires 1024 bytes of display buffer and the Ink Layer requires (display width x display height ÷ 4) bytes of display buffer.
8.2 Registers

<table>
<thead>
<tr>
<th>REG[070h] LCD Ink/Cursor Control Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>REG[080h] CRT/TV Ink/Cursor Control Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
</tr>
</tbody>
</table>

The Ink/Cursor mode bits determine which of the Hardware Cursor or Ink Layer is active as shown in following table.

**Table 8-1: Ink/Cursor Mode**

<table>
<thead>
<tr>
<th>Ink/Cursor Control</th>
<th>Operating Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>bit 1</td>
<td>bit 0</td>
</tr>
<tr>

<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

**Note**
When cursor mode is selected the cursor image is always 64x64 pixels. Selecting an ink layer will result in an area which completely covers the display.

<tbody>
<tr>
<td>CRT/TV Ink/Cursor Start Address Bit 7</td>
</tr>
</tbody>
</table>

REG[071h] and REG[081h] determine the display buffer location of the Hardware Cursor/Ink Layer for the LCD and CRT/TV respectively. The Ink/Cursor Start Address register does not contain an actual address, but a value based on the following table.

**Table 8-2: Cursor/Ink Start Address Encoding**

<table>
<thead>
<tr>

<th>CRT/TV Cursor X Position Bit 8</th>
</tr>
</thead>
</table>

REG\[072h\], REG\[073h\] and REG\[082h\], REG\[083h\] control the horizontal position of the Hardware Cursor for the LCD and CRT/TV respectively. The value in these registers specify the location of the left edge of the cursor. When ink mode is selected these registers must be set to zero.

The Cursor X Position supports values of the range -63 to 1023. Negative values allow for the Cursor to be clipped (partially off the screen). The following procedure sets the Cursor X Position.

1. Write the absolute (non-negative) value of the position in bits 9-0.
2. If the position is negative, write a 1 in the Cursor X Sign bit; otherwise write a 0 to the sign bit.
REG[074h] LCD Cursor Y Position Register 0

<th>CRT/TV Cursor Y Position Bit 8</th>
</tr>
</thead>
</table>

REG[074h], REG[075h] and REG[084h], REG[085h] control the vertical position of the Hardware Cursor for the LCD and CRT/TV respectively. The value in these registers specify the location of the top edge of the cursor. When ink mode is selected these registers must be set to zero.

The Cursor Y Position supports values of the range -63 to 1023. Negative values allow for the Cursor to be clipped (partially off the screen). The following procedure sets the Cursor X Position.

1. Write the absolute (non-negative) value of the position in bits 9-0.
2. If the position is negative, write a 1 in the Cursor Y Sign bit; otherwise write a 0 to the sign bit.
These registers form the 16 bpp (5-6-5) RGB values of user-defined color 0 for the LCD Ink Layer/Hardware Cursor.

These registers form the 16 bpp (5-6-5) RGB values of user-defined color 1 for the LCD Ink Layer/Hardware Cursor.
These registers form the 16 bpp (5-6-5) RGB values of user-defined color 0 for the CRT/TV Ink Layer/Hardware Cursor.

</tr>
</thead>
<tbody>
<tr>
<td>n/a</td>
</tr>
</tbody>
</table>
These registers control the Ink Layer/Hardware Cursor FIFO depth in order to sustain uninterrupted display fetches.

REG[07Eh] determines the FIFO high threshold for the LCD Hardware Cursor/Ink Layer. REG[08Eh] determines the FIFO high threshold for the CRT/TV Hardware Cursor/Ink Layer. When this register is set to 00h, the threshold is automatically set in hardware. For further information, see the 13506 Hardware Functional Specification, document number X25B-A-001-xx.
8.3 Initialization

This section describes the process of initializing the S1D13506 for a Hardware Cursor or Ink Layer.

8.3.1 Memory Considerations

Both the Hardware Cursor and Ink Layer are positioned in the display buffer by the LCD Ink/Cursor Start Address register (REG[071h]) and CRT/TV Ink/Cursor Start Address register (REG[081h]). The Hardware Cursor and Ink Layer should be allocated the highest possible available memory address. If a Dual Panel Buffer is required, or if another Hardware Cursor or Ink Layer is required, additional memory must be allocated and programmed in the appropriate Ink/Cursor Start Address register.

The size of the Dual Panel Buffer is determined by the following.

\[
\text{Dual Panel Buffer Size (in bytes)} = (\text{Panel Width} \times \text{Panel Height}) \times \text{factor} \div 16
\]

where:

- \text{factor} = 4 \text{ for color panel}
- \text{factor} = 1 \text{ for monochrome panel}

**Note**

The dual panel buffer always starts at (Display Memory Size - Dual Panel Buffer Size).

The size of a hardware cursor is always 1024 bytes.
The size of the ink layer in bytes is (display width \times display height \div 4).
8.3.2 Examples

**Example 5: Initializing the Hardware Cursor**

The following example places an LCD Hardware Cursor at the end of a 2M byte display buffer. SwivelView™ modes require software rotation of the Ink Layer. This can only occur when a Dual Panel Buffer is not required. Color 0 is set to black, and color 1 is set to white.

**Note**

The Hardware Cursor always requires 1024 (400h) bytes.

<td>Set FIFO High Threshold to default</td>
</tr>
</tbody>
</table>
**Example 6: Initializing the Ink Layer**

The following example places an Ink Layer at the end of a 2M byte display buffer. SwivelView™ modes require software rotation of the Ink Layer. Color 0 is set to black, and color 1 is set to white.

For a system with a 640x480 LCD display, the ink layer size is calculated as follows.

\[
\text{InkLayerSize} = \frac{\text{PanelWidth} \times \text{PanelHeight}}{4} = \frac{640 \times 480}{4} = 76,800 \text{ bytes}
\]

The Ink Layer must be allocated in 8K byte blocks. The value of the LCD Ink/Cursor Start Address register is determined from the following table and calculation.

\[
n = \frac{\text{InkLayerSize}}{\text{RequiredBlockSize}} = \frac{76,800}{8192} = 9.375
\]

Fractional values cannot be programmed, therefore round up to an address of 10 (0Ah). This reserves 10 x 8192 = 81,920 bytes for the Ink Layer from the end of display buffer.

**Note**
Always round up the Ink/Cursor Start Address when calculating, otherwise insufficient memory will be allocated for the Ink Layer.

**Table 8-4: Ink Layer Start Address Encoding**

8.4 Writing Cursor/Ink Layer Images

This section describes how to write images to the Hardware Cursor and Ink Layer. The Hardware Cursor is a 64x64 image at a color depth of 2 bpp. The Ink Layer is the same size as the virtual display (width x height) at a color depth of 2 bpp. The Ink Layer may be described as a non-moveable cursor with the same resolution as the display device.

8.4.1 Hardware Cursor/Ink Layer Data Format

The Hardware Cursor/Ink Layer image is fixed at a color depth of 2 bpp. The following diagram shows the Hardware Cursor/Ink Layer data format for a little endian system.

![Diagram](image)

**Figure 8-1: Hardware Cursor/Ink Layer Data Format**

The image data for pixel n, \((A_n, B_n)\), selects the color for pixel n as follows:

<table>
<thead>
<tr>

</tbody>
</table>
8.4.2 Cursor Image

The following procedures demonstrate how to write an image to the Hardware Cursor buffer.

Landscape Mode (no rotation)

1. For the LCD cursor, calculate the start address based on the value in REG[071h]. For the CRT/TV cursor, calculate the start address based on the value in REG[081h]. Refer to the REG[071h] and REG[081h] register descriptions for more information.
2. Write the cursor image to the display buffer. The image must be exactly 1024 bytes.

SwivelView Modes

1. Save the current state of REG[1FCh] bit 6.
2. Set REG[1FCh] bit 6 to 0.
3. For the LCD cursor, calculate the start address based on the value in REG[071h]. For the CRT/TV cursor, calculate the start address based on the value in REG[081h]. Refer to the REG[071h] and REG[081h] register descriptions for more information.
4. Perform a software rotate of the cursor image.
5. Write the rotated cursor image to the display buffer. The image must be exactly 1024 bytes.
6. Restore the original state of REG[1FCh] bit 6.

Note

It is possible to use the same cursor image for both LCD and CRT/TV displays. Program the LCD and CRT/TV Ink/Cursor Start Address registers (REG[071h] and REG[081h]) to the same location. This saves some display buffer which would otherwise be used by a second cursor image. Note this saves 8192 bytes of display buffer, not 1024 bytes, because the start address moves in steps of 8192 bytes.
8.4.3 Ink Layer Image

The following procedures demonstrate how to write an image to the Ink Layer buffer.

**Landscape Mode (no rotation)**

1. For the LCD, calculate the start address based on the value in REG[071h].
   For the CRT/TV, calculate the start address based on the value in REG[081h].
   Refer to the REG[071h] and REG[081h] register descriptions for more information.

2. Write the Ink Layer image to the display buffer. The image must be exactly (display width x display height ÷ 4) bytes.

**SwivelView Modes**

1. Save the current state of REG[1FCh] bit 6.

2. Set REG[1FCh] bit 6 to 0.

3. For the LCD, calculate the start address based on the value in REG[071h].
   For the CRT/TV, calculate the start address based on the value in REG[081h].
   Refer to the REG[071h] and REG[081h] register descriptions for more information.

4. Perform a software rotate of the Ink Layer image.

5. Write the rotated Ink Layer image to the display buffer. The image must be exactly (display width x display height ÷ 4) bytes.

6. Restore the original state of REG[1FCh] bit 6.

**Note**

It is possible to use the same Ink Layer image for both LCD and CRT/TV displays. Program the LCD and CRT/TV Ink/Cursor Start Address registers (REG[071h] and REG[081h]) to the same location. This saves some display buffer which would otherwise be used by a second Ink Layer.
8.5 Cursor Movement

The following section discusses cursor movement in landscape, SwivelView 90°, SwivelView 180°, and SwivelView 270° modes.

It is possible to move the top left corner of the cursor to a negative position (-63, -63). This allows the cursor to be clipped (only a portion is visible on-screen).

Cursor positions don’t take effect until the most significant byte of the Y position register is written. Therefore, the following register write order is recommended.

1. Set X Position Register 0
2. Set X Position Register 1
3. Set Y Position Register 0
4. Set Y Position Register 1.

8.5.1 Move Cursor in Landscape Mode (no rotation)

In the following example, (x, y) represents the desired cursor position.

1. Calculate abs(x), the absolute (non-negative) value of x.
2. Write the least significant byte of abs(x) to X Position Register 0.
3. If x is negative, take the value of the most significant byte of abs(x) and logically OR with 80h. Write the result to X Position Register 1.
   If x is positive, write the most significant byte of abs(x) to X Position Register 1.
4. Calculate abs(y), the absolute (non-negative) value of y.
5. Write the least significant byte of abs(y) to Y Position Register 0.
6. If y is negative, take the value of the most significant byte of abs(y) and logically OR with 80h. Write the result to Y Position Register 1.
   If y is positive, take the value of the most significant byte of abs(y) and write to Y Position Register 1.
8.5.2 Move Cursor in SwivelView 90° Rotation

In the following example, \((x, y)\) represent the desired cursor position.

1. Calculate \(\text{abs}(x)\), the absolute (non-negative) value of \(x\).
2. Write the least significant byte of \(\text{abs}(x)\) to Y Position Register 0.
3. If \(x\) is negative, take the value of the most significant byte of \(\text{abs}(x)\) and logically OR with \(80\text{h}\). Write the result to Y Position Register 1.
   If \(x\) is positive, write the most significant byte of \(\text{abs}(x)\) to Y Position Register 1.
4. Calculate a value for \(y_2\),
   where \(y_2 = \text{display width} - y - 64\).
5. Calculate \(\text{abs}(y_2)\), the absolute (non-negative) value of \(y_2\).
6. Write the least significant byte of \(\text{abs}(y_2)\) to X Position Register 0.
7. If \(y_2\) is negative, take the value of the most significant byte of \(\text{abs}(y_2)\) and logically OR with \(80\text{h}\). Write the result to X Position Register 1.
   If \(y_2\) is positive, write the most significant byte of \(\text{abs}(y_2)\) to X Position Register 1.

8.5.3 Move Cursor in SwivelView 180° Rotation

In the following example, \((x, y)\) represent the desired cursor position.

1. Calculate the value of \(x_2\),
   where \(x_2 = \text{display width} - x - 64\)
2. Calculate \(\text{abs}(x_2)\), the absolute (non-negative) value of \(x_2\).
3. Write the least significant byte of \(\text{abs}(x_2)\) to X Position Register 0.
4. If \(x_2\) is negative, take the value of the most significant byte of \(\text{abs}(x_2)\) and logically OR with \(80\text{h}\). Write the result to X Position Register 1.
   If \(x_2\) is positive, write the most significant byte of \(\text{abs}(x_2)\) to X Position Register 1.
5. Calculate the value of \(y_2\),
   where \(y_2 = \text{display height} - y - 64\)
6. Calculate \(\text{abs}(y_2)\), the absolute (non-negative) value of \(y_2\).
7. Write the least significant byte of \(\text{abs}(y_2)\) to Y Position Register 0.
8. If \(y_2\) is negative, take the value of the most significant byte of \(\text{abs}(y_2)\) and logically OR with \(80\text{h}\). Write the result to Y Position Register 1.
   If \(y_2\) is positive, write the most significant byte of \(\text{abs}(y_2)\) to Y Position Register 1.
8.5.4 Move Cursor in SwivelView 270° Rotation

In the following example, (x, y) represent the desired cursor position.

1. Calculate the value of x₂,
   
   where x₂ = display width - x - 64

2. Calculate abs(x₂), the absolute (non-negative) value of x₂.

3. Write the least significant byte of abs(x₂) to Y Position Register 0.

4. If x₂ is negative, take the value of the most significant byte of abs(x₂) and logically OR with 80h. Write the result to Y Position Register 1.
   If x₂ is positive, write the most significant byte of abs(x₂) to Y Position Register 1.

5. Calculate abs(y), the absolute (non-negative) value of y.

6. Write the least significant byte of abs(y) to X Position Register 0.

7. If y is negative, take the value of the most significant byte of abs(y) and logically OR with 80h. Write the result to X Position Register 1.
   If y is positive, write the most significant byte of abs(y) to X Position Register 1.
9 SwivelView™

Most computer displays operate in landscape mode. In landscape mode the display is wider than it is high. For example, a standard display size of 640x480 is 640 pixels wide and 480 pixels wide.

SwivelView rotates the display image clockwise in ninety degree increments, possibly resulting in a display that is higher than it is wide. Rotating the image on a 640x480 display by 90 or 270 degrees yields a display that is now 480 pixels wide and 640 pixels high.

SwivelView also works with panels that are designed with a "portrait" orientation. In this case, when SwivelView 0° is selected, the panel will be in a “portrait” orientation. A selection of SwivelView 90° or SwivelView 270° rotates to a landscape orientation.

9.1 S1D13506 SwivelView

The S1D13506 provides hardware support for SwivelView in 8, 15 and 16 bpp color depths on LCD panels. SwivelView is not supported on CRT or TV displays.

Certain conditions must be considered when SwivelView is enabled.

- The virtual display offset (scan line) must be set to 1024 pixels (1024 bytes in 8 bpp, 2048 bytes in 15/16 bpp) when SwivelView Enable Bit 0 is set to 1.
- The display start address is calculated differently when SwivelView is enabled.
- Calculations that would result in panning in landscape mode, may result in scrolling when SwivelView is enabled and vice-versa.

9.2 Registers

<table>
<thead>
<tr>
<th>REG[01FCh] Display Mode Register</th>
<th>n/a</th>
<th>SwivelView Enable Bit 0</th>
<th>n/a</th>
<th>n/a</th>
<th>n/a</th>

<td>n/a</td>
<td>SwivelView Enable Bit 1</td>
<td>n/a</td>
<td>Bit-Per-Pixel Select Bit 2</td>
<td>Bit-Per-Pixel Select Bit 1</td>
</tr>
</tbody>
</table>

The SwivelView modes are enabled using a combination of 2 enable bits - SwivelView Enable Bit 0 (REG[1FCh]) and SwivelView Enable Bit 1 (REG[040h]). The combinations of these bits provide the following rotations.
The LCD Memory Address Offset Registers must be adjusted according to the desired SwivelView rotation and color depth. Set the LCD Memory Address Offset Registers based on the values provided for each color depth in the following table. Panel Width (PW) is the horizontal panel size in pixels (i.e. for a 640x480 panel, PW is 640 regardless of the display rotation).

</tbody>
</table>
The LCD Display Start Address Registers must be adjusted according to the desired SwivelView rotation and color depth. Set the LCD Display Start Address Registers based on the values provided for each color depth in the following table. Panel Width (PW) is the horizontal panel size in pixels. Panel Height (PH) is the vertical panel size in lines (i.e. for a 640x480 panel, PW is 640 and PH is 480 regardless of display rotation). Stride is the based on the previously calculated memory offset in bytes (Stride = MemoryOffset × 2).

</tbody>
</table>

#### 9.3 Limitations

The following limitations apply when SwivelView bit 0 is set to 1 (rotation by 90° or 270°):

- Only 8/15/16 bpp modes can be rotated 90 or 270 degrees.
- Hardware Cursor and Ink Layer images are not rotated - software rotation must be used. SwivelView must be turned off when the programmer is accessing the Hardware Cursor or the Ink Layer. The blit engine ignores the SwivelView bits also.
- Pixel panning works vertically.
- It is not possible to rotate an already displayed image. The image must be redrawn.

**Note**

Drawing into the Hardware Cursor/Ink Layer with SwivelView enabled requires disabling SwivelView, drawing in the Hardware Cursor/Ink Layer buffer, then re-enabling SwivelView.
9.4 Examples

Source code demonstrating various SwivelView rotations is provided in the file 13506swivel.c available on the internet at www.eea.epson.com.

Example 7: Rotate Image 90° for a 640x480 display at a color depth of 8 bpp.

Before enabling SwivelView, the display buffer should be cleared. This makes the transition smoother as existing display images cannot be rotated by hardware - a repaint is necessary.

1. Set the line offset to 1024 pixels. The Memory Offset register is the offset in words.
   
   Write 02h to REG[047h] and write 00h to REG[046h].

2. Set the LCD Display Start Address. The Display Start Address registers form a pointer to a word, therefore the value to set the start.
   
   Write C0h (192 or (1024 - 480)÷2) to REG[042h], REG[043h] and REG[044h]. That is write C0h) to REG[042h], 00h to REG[043h] and 00h to REG[044h].

3. Enable SwivelView Bit 0 and clear SwivelView Bit 1. Set REG[1FCh] to 1 and REG[040h] to 0.

4. The display is now configured for SwivelView 90° mode. Offset zero into the display buffer corresponds to the upper left corner of the display. The only difference seen by the programmer is the display offset is now 1024 pixels regardless of the physical dimensions of the display.

5. Draw the desired image.

Example 8: Rotate Image 180 degrees for a 640x480 display at a color depth of 16 bpp.

Assuming the existing image is unrotated, the display buffer does not have to be cleared. Existing display images are simply be rotated by hardware. In this case a repaint is not necessary.

1. The Memory Offset register does not need to be modified.

2. Set the LCD Display Start Address. The Display Start Address registers form a pointer to a word, therefore the value to set the start. Calculate the value based on the following formula.

   StartAddress = (ScanBytes \times PanelHeight - (ScanBytes - 2 \times PanelWidth)) \div 2 - 1
   = (1280 \times 480 - (1280 -2 \times 640)) \div 2 - 1
   = (1280 \times 480) \div 2 - 1
   = 307199
   = 4AFFFh
Program the LCD Display Start Address Registers. REG[044h] is set to 04h, REG[043h] is set to AFh, and REG[042h] is set to FFh.

3. Set SwivelView Bit 1 by setting bit 4 of REG[040h]

4. The display will now show the previous image rotated by 180 degrees. Offset zero into display memory will correspond to the lower right corner of the display.

5. Draw any new desired image. The drawing software can be completely unaware of the display being rotated.

9.5 Simultaneous Display Considerations

Although only the LCD panel image can be rotated, it is possible to simultaneously display an independent image on the CRT or TV display. In this case, the programmer should be aware of the following:

• As the LCD display buffer must start at offset 0 when a rotated display is required, the CRT display buffer must be located after the LCD display buffer.

• When modifying the CRT display buffer, SwivelView Enable Bit 0 must be cleared and then restored when finished. The following demonstrates this principle.

1. Save SwivelView Bit 0
2. Clear SwivelView Bit 0
3. Draw the CRT/TV image
4. Restore the saved SwivelView Bit 0.
10 2D BitBLT Engine

The term BitBLT is an acronym for Bit Block Transfer. During a BitBLT operation data is transferred from one memory location (source) to another memory location (destination). With current graphical user interfaces (GUIs) this term generally refers to the transfer of bitmap images to or from video memory (display buffer).

The resulting bitmap image may be derived from up to three items or operands:

- the source data.
- an optional pattern.
- the current destination data.

The operands are combined using logical AND, OR, XOR and NOT operations. The combining process is called a Raster Operation (ROP). The S1D13506 2D Accelerator supports all possible 16 ROPs between source data and destination data. The destination is always the display buffer and the source is either data in the display buffer, a pattern in the display buffer, or data provided by the host CPU.

The 2D BitBLT Engine in the S1D13506 is designed to increase the speed of the most common GUI operations by off-loading work from the CPU, thus reducing traffic on the system bus and improving the efficiency of the display buffer interface. The 2D BitBLT Engine is designed to work at color depths of 8 bpp, 15 bpp, and 16 bpp.

10.1 Registers

The BitBLT control registers on the S1D13506 are located at registers 100h through 119h. The following is a description of all BitBLT registers.

<table>
<thead>
<tr>
<th>REG[100h] BitBLT Control Register 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>BitBLT Active Status</td>
</tr>
</tbody>
</table>

The BitBLT Active Status bit has two data paths, one for write and one for read.

**Write Data Path**
When this bit is set to 1, the BitBLT as selected in the BitBLT Operation Register (REG[103h]) is started.

**Read Data Path**
When this bit is read, it returns the status of the blit engine. When a read from this bit returns 0, the blit engine is idle and is ready for the next operation. When a read from this bit returns a 1, the blit engine is busy.
The BitBLT FIFO Not Empty Status bit is a read-only status bit. When this bit returns a 0, the BitBLT FIFO is empty. When this bit returns a 1, the BitBLT FIFO contains at least one data.

The BitBLT FIFO Half Full Status bit is a read-only status bit. When this bit returns a 0, the BitBLT FIFO is less than half full (contains 7 or less data). When this bit returns a 1, the BitBLT FIFO is half full or greater than half full (contains 8 or more data).

The BitBLT FIFO Full Status bit is a read-only status bit. When this bit returns a 0, the BitBLT FIFO is not full (contains less than 16 data). When this bit returns a 1, the BitBLT FIFO is full (contains 16 data).

The BitBLT Destination Linear Select bit specifies the storage method of the destination blit. If this bit = 0, the destination blit is stored as a rectangular region of memory. If this bit = 1, the destination blit is stored as a contiguous linear block of memory.

The BitBLT Source Linear Select bit specifies the storage method of the source blit. If this bit = 0, the source blit is stored as a rectangular region of memory. If this bit = 1, the source blit is stored as a contiguous linear block of memory.

</tbody>
</table>

The BitBLT Source Start Address Registers form a 21-bit register that specifies the source start address for the BitBLT operation selected by the BitBLT Operation Register (REG[103h]).
If data is sourced from the CPU, then bit 0 is used for byte alignment within a 16-bit word and the other address bits are ignored. In pattern fill operation, the BitBLT Source Start Address is defined by the following equation:

Source Start Address Register = Pattern Base Address + Pattern Line Offset + Pixel Offset.

The following table shows how Source Start Address Register is defined for 8 and 16 bpp color depths:

\[
\begin{array}{|c|c|c|}
\hline
\text{Color Format} & \text{Pattern Base Address[20:0]} & \text{Pattern Line Offset[2:0]} & \text{Pixel Offset[3:0]} \\
\hline
8 \text{ bpp} & \text{BitBLT Source Start Address[20:6], 6'b0} & \text{BitBLT Source Start Address[5:3]} & \text{1'b0, BitBLT Source Start Address[2:0]} \\
16 \text{ bpp} & \text{BitBLT Source Start Address[20:7], 7'b0} & \text{BitBLT Source Start Address[6:4]} & \text{BitBLT Source Start Address[3:0]} \\
\hline
\end{array}
\]

The BitBLT Destination Start Address Registers form a 21-bit register that specifies the destination start address for the BitBLT operation selected by the BitBLT Operation Register (REG[103h]). The destination address represents the upper left corner of the BitBLT rectangle (lower right corner of the BitBLT rectangle for Move Blit in Negative Direction).
The BitBLT Memory Address Offset Registers form the BitBLTs 11-bit address offset from the starting word of line “n” to the starting word of line “n + 1”. They are used for address calculation only when the BitBLT is configured as a rectangular region of memory using the BitBLT Destination/Source Linear Select bits (REG[100h] bits 1-0). They are not used for the displays.

The BitBLT Width Registers form a 10-bit register that specifies the BitBLT width in pixels less 1.

**Note**
The BitBLT operations Pattern Fill with ROP and Pattern Fill with transparency require a BitBLT Width ≥ 2.

The BitBLT Height Registers form a 10-bit register that specifies the BitBLT height in pixels less 1.
The BitBLT Background Color Registers form a 16-bit register that specifies the BitBLT background color for Color Expansion or the key color for transparent blits. For 16 bpp color depth (REG[101h] bit 0 = 1), all 16 bits are used. For 8 bpp color depth (REG[101h] bit 0 = 0), only bits 7-0 are used.

The BitBLT Foreground Color Registers form a 16-bit register that specifies the BitBLT foreground color for Color Expansion or the Solid Fill BitBLT. For 16 bpp color depth (REG[101h] bit 0 = 1), all 16 bits are used. For 8 bpp color depth (REG[101h] bit 0 = 0), only bits 7-0 are used.
10.2 BitBLT Descriptions

The S1D13506 supports 13 fundamental BitBLT operations:

- Write Blit with ROP.
- Read Blit.
- Move Blit in positive direction with ROP.
- Move Blit in negative direction with ROP.
- Transparent Write Blit.
- Transparent Move Blit in positive direction.
- Pattern Fill with ROP.
- Pattern Fill with Transparency.
- Color Expansion.
- Color Expansion with Transparency.
- Move Blit with Color Expansion.
- Move Blit with Color Expansion and Transparency.
- Solid Fill.

Most of the 13 operations are self completing. This means once they begin they complete on their own, not requiring data transfers with the CPU. The remaining five BitBLT operations (Write Blit with ROP, Transparent Write Blit, Color Expansion, Color Expansion with Transparency, Read Blit) require data to be written/read to/from the display buffer. This data must be transferred one word (16-bits) at a time. This does not imply only 16-bit CPU instructions are acceptable. If a system is able to separate one DWORD write into two WORD writes, then 32-bit CPU instructions are acceptable. Otherwise, two back to back 16-bit CPU instructions are required.

The data is not directly written/read to/from the display buffer. It is written/read to/from the BitBLT FIFO through the 1M blit aperture specified at the address of REG[100000h]. The 16 word FIFO can be written to only when not full and can be read from only when not empty. Failing to monitor the FIFO status can result in a BitBLT FIFO overflow or underflow.

While the FIFO is being written to by the CPU, it is also being emptied by the S1D13506. If the S1D13506 empties the FIFO faster than the CPU can fill it, it may not be possible to cause an overflow/underflow. In these cases, performance can be improved by not monitoring the FIFO status. However, this is very much platform dependent and must be determined for each system.

**Note**

When TV with flicker filter is enabled or simultaneous display is active, always test the FIFO status before reading from/writing to the FIFO.
10.2.1 Write Blit with ROP

The Write Blit increases the speed of transferring data from system memory to the display buffer.

The Write Blit with ROP fills a specified area of the display buffer with data supplied by the CPU. This blit is typically used to copy a bitmap image from system memory to the display buffer. The Write Blit supports all 16 ROPs, although the most frequent ROP is ROP 0Ch (Copy Source into Destination). It also supports both Destination Linear and Destination Rectangular modes.

The Write Blit requires the CPU to provide data. The blit engine expects to receive a certain number of WORDS. For 15/16 bpp color depths, the number of WORDS is the same as the number of pixels due to the fact that each pixel is one WORD wide. The number of WORD writes the blit engine expects is calculated using the following formula.

\[ n\text{WORDS} = n\text{Pixels} = \text{BlitWidth} \times \text{BlitHeight} \]

For 8 bpp color depths, the formula must take into consideration that the blit engine accepts only WORD accesses and each pixel is one BYTE. The blit engine needs to know whether the first pixel of a line is stored in the low byte or high byte. This is determined by bit 0 of the Source Start Address Register 0 (REG[104h]). If the Source Phase is 1 (bit 0 of the Source Start Address Register 0 is set), the first pixel of each line is in the high byte of the WORD and the contents of the low byte are ignored. If the Source Phase is 0, the first pixel is in the low byte and the second pixel is in the high byte. Depending on the Source Phase and the Blit Width, the last WORD may contain only one pixel. In this case it is always in the low byte. The number of WORD writes the blit engine expects for 8 bpp color depths is shown in the following formula.

\[ n\text{WORDS} = \left(\frac{\text{BlitWidth} + 1 + \text{SourcePhase}}{2}\right) \times \text{BlitHeight} \]

**Note**

The blit engine counts WORD writes in the blit address space. This does not imply only 16-bit CPU instructions are acceptable. If a system is able to separate one DWORD write into two WORD writes, then 32-bit CPU instructions are acceptable. Otherwise, two back to back 16-bit CPU instructions are required.
Example 9: Write a 100 x 20 rectangle at the screen coordinates x = 25, y = 38 using a 640x480 display at a color depth of 8 bpp.

1. Calculate the destination address (upper left corner of the screen blit rectangle) using the following formula.

\[
\text{DestinationAddress} = (y \times \text{ScreenStride}) + (x \times \text{BytesPerPixel})
\]

\[
= (38 \times 640) + (25 \times 1)
\]

\[
= 24345
\]

\[
= 5F19h
\]

where:

- \(\text{BytesPerPixel} = 1\) for 8 bpp
- \(\text{BytesPerPixel} = 2\) for 15/16 bpp
- \(\text{ScreenStride} = \text{DisplayWidthInPixels} \times \text{BytesPerPixel} = 640\) for 8 bpp

Program the BitBLT Destination Start Address Registers. REG[10Ah] is set to 00h, REG[109h] is set to 5Fh, and REG[108h] is set to 19h.

2. Program the BitBLT Width Registers to 100 - 1. REG[111h] is set to 00h and REG[110h] is set to 63h (99 decimal).

3. Program the BitBLT Height Registers to 20 - 1. REG[113h] is set to 00h and REG[112h] is set to 13h (19 decimal).

4. Program the Source Phase in the BitBLT Source Start Address Register. In this example the data is WORD aligned, so the source phase is 0. REG[104h] is set to 00h.

5. Program the BitBLT Operation Register to select the Write Blit with ROP. REG[103h] is set to 00h.

6. Program the BitBLT ROP Code Register to select Destination = Source. REG[102h] is set to 0Ch.

7. Program the BitBLT Color Format Select bit for 8 bpp operations. REG[101h] is set to 00h.

8. Program the BitBLT Memory Offset Registers to the ScreenStride in WORDS:

\[
\text{BltMemoryOffset} = \text{DisplayWidthInPixels} \div \text{BytesPerPixel}
\]

\[
= 640 \div 2
\]

\[
= 140h
\]

REG[10Dh] is set to 01h and REG[10Ch] is set to 40h.

9. Calculate the number of WORDS the blit engine expects to receive.

\[
\text{nWORDS} = ((\text{BlitWidth} + 1 + \text{SourcePhase}) \div 2) \times \text{BlitHeight}
\]

\[
= (100 + 1) \div 2 \times 20
\]

\[
= 1000
\]

\[
= 3E8h
\]
10. Program the BitBLT Destination/Source Linear Select bits for a rectangular blit (BitBLT Destination Linear Select = 0, BitBLT Source Linear Select = 0).

Start the blit operation and wait for the blit engine to start. REG[100h] is set to 80h, then wait until REG[100h] bit 7 returns a 1.

11. Prior to writing all nWORDS to the Blit FIFO, confirm the Blit FIFO is not full (REG[100h] bit 4 returns a 0). If the BitBLT FIFO Not Empty Status returns a 0 (the FIFO is empty), write up to 16 WORDS. If the BitBLT FIFO Not Empty Status returns a 1 and the BitBLT FIFO Half Full Status returns a 0 then you can write up to 8 WORDS. If the BitBLT FIFO Full Status returns a 1, do not write to the BitBLT FIFO until it returns a 0.

The following table summarizes how many words can be written to the Blit FIFO.

<table>
<thead>
<tr>
<th>BitBLT Control Register 0 (REG[100h])</th>
<th>Word Writes Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIFO Not Empty Status</td>
<td>FIFO Half Full Status</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Note
The order of register initialization is irrelevant as long as all relevant registers are programmed before the BitBLT is started.

10.2.2 Color Expand BitBLT

This Color Expand BitBLT is similar to the Write BitBLT. It differs in that a bit set to 1 in the source data becomes a pixel of foreground color. A source bit set to 0 is converted to a pixel of background color. This function increases the speed of writing text while in graphical modes.

This BitBLT operation includes several options which enhance its text handling capabilities. As with the Write BitBLT, all data sent to the blit engine must be word (16-bit) writes. **The blit engine expands the low byte, then the high byte starting at bit 7 of each byte.**

The start byte of the first WORD to be expanded and the start bit position within this byte must be specified. The start byte position is selected by setting source address bit 0 to 0 to start expanding the low byte or 1 to start expanding the high byte.
Partially “masked” color expand BitBLT can be used when drawing a portion of a pattern (i.e. a portion of a character) on the screen. The following examples illustrate how one WORD is expanded using the Color Expand BitBLT.

1. To expand bits 0-1 of the word:
   
   Source Address = 0
   Start Bit Position = 1
   Blit Width = 2

   The following bits are expanded.

2. To expand bits 0-15 of the word (entire word)
   
   Source Address = 0
   Start Bit Position = 7 (bit seven of the low byte)
   Blit Width = 16

   The following bits are expanded.

3. To expand bits 8-9 of the word
   
   Source Address = 1
   Start Bit Position = 1
   Blit Width = 2

   The following bits are expanded.

4. To expand bits 0,15-14 of the word
Source Address = 0
Start Bit Position = 0
Blit Width = 3

The following bits are expanded.

All subsequent WORDS in one blit line are then serially expanded starting at bit 7 of the low byte until the end of the blit line. All unused bits in the last WORD are discarded. It is extremely important that the exact number of WORDS is provided to the blit engine. The number of WORDS is calculated from the following formula. This formula is valid for all color depths (8/15/16 bpp).

\[
n\text{Words} = \left(\frac{S_x \mod 16 + \text{BltWidth} + 15}{16}\right) \times \text{BltHeight}
\]

where:
Sx is the X coordinate of the starting pixel in a word aligned monochrome bitmap.

**Example 10:** Color expand a rectangle of 12 x 18 starting at the coordinates Sx = 125, Sy = 17 using a 640x480 display at a color depth of 8 bpp.

This example assumes a monochrome, WORD aligned bitmap of dimensions 300 x 600 with the origin at an address A. The color expanded rectangle will be displayed at the screen coordinates X = 20, Y = 30. The foreground color corresponds to the LUT entry at index 134, the background color to index 124.

1. First we need to calculate the address of the WORD within the monochrome bitmap containing the pixel x = 125, y = 17.

\[
\text{SourceAddress} = \text{BitmapOrigin} + (y \times \text{SourceStride}) + (x \div 8)
\]
\[
= A + (Sy \times \text{SourceStride}) + (Sx \div 8)
\]
\[
= A + (17 \times 38) + (125 \div 8)
\]
\[
= A + 646 + 15
\]
\[
= A + 661
\]
where:
SourceStride = (BitmapWidth + 15) ÷ 16
= (300 + 15) ÷ 16
= 19 WORDS per line
= 38 BYTES per line

2. Calculate the destination address (upper left corner of the screen blit rectangle) using the following formula.

\[
\text{DestinationAddress} = (Y \times \text{ScreenStride}) + (X \times \text{BytesPerPixel})
\]
\[
=(30 \times 640) + (20 \times 1)
\]
\[
= 19220
\]
\[
= 4B14h
\]

where:
BytesPerPixel = 1 for 8 bpp
BytesPerPixel = 2 for 15/16 bpp
ScreenStride = DisplayWidthInPixels × BytesPerPixel = 640 for 8 bpp

Program the BitBLT Destination Start Address Registers. REG[10Ah] is set to 00h, REG[109h] is set to 4Bh, and REG[108h] is set to 14h.

3. Program the BitBLT Width Registers to 12 - 1. REG[111h] is set to 00h, REG[110h] is set to 0Bh (11 decimal).

4. Program the BitBLT Height Registers to 18 - 1. REG[113h] is set to 00h, REG[112h] is set to 11h (17 decimal).

5. Program the Source Phase in the BitBLT Source Start Address Register. In this example the source address equals A + 661 (odd), so REG[104h] is set to 1.

Since only bit 0 flags the source phase, more efficient code would simply write the low byte of the SourceAddress into REG[104h] directly -- not needing to test for an odd/even address. Note that in 15/16 bpp color depths the Source address is guaranteed to be even.

6. Program the BitBLT Operation Register to select the Color Expand Blit. REG[103h] is set to 08h.

7. Program the Color Expansion Register. The formula for this example is as follows.

\[
\text{Reg}[102h] = 7 - (Sx \text{ MOD } 8)
\]
\[
= 7 - (125 \text{ MOD } 8)
\]
\[
= 7 - 5
\]
\[
= 2
\]

REG[102h] is set to 02h.

8. Program the Background Color Registers to the background color. REG[115h] is set to 00h and REG[114h] is set to 7Ch (124 decimal).

Note that for 15/16 bpp color depths, REG[115h] and REG[114h] are both required and programmed directly with the value of the background color.
9. Program the Foreground Color Registers to the foreground color. REG[119h] is set to 00h and REG[118h] is set to 86h (134 decimal).

Note that for 15/16 bpp color depths REG[119h] and REG[118h] are both required and programmed directly with the value of the foreground color.

10. Program the BitBLT Color Format Register for 8 bpp operation. REG[101h] is set to 00h.

11. Program the BitBLT Memory Offset Registers to the ScreenStride in WORDS.

\[
\text{BltMemoryOffset} = \frac{\text{ScreenStride}}{2} = \frac{640}{2} = 140\text{h}
\]

REG[10Dh] is set to 01h and REG[10Ch] is set to 40h.

12. Calculate the number of WORDS the blit engine expects to receive.

First, the number of WORDS in one blit line must be calculated as follows.

\[
\text{nWordsOneLine} = \frac{(125 \mod 16) + 12 + 15}{16} = \frac{40}{16} = 2
\]

Therefore, the total WORDS the blit engine expects to receive is calculated as follows.

\[
\text{nWords} = \text{nWordsOneLine} \times 18 = 2 \times 18 = 36
\]

13. Program the BitBLT Destination/Source Linear Select bits for a rectangular blit (BitBLT Destination Linear Select = 0, BitBLT Source Linear Select = 0).

Start the blit operation and wait for the Blit Engine to start. REG[100h] is set to 80h, then wait until REG[100h] bit 7 returns a 1.

14. Prior to writing all nWORDS to the Blit FIFO, confirm the Blit FIFO is not full (REG[100h] bit 4 returns a 0). One WORD expands into 16 pixels which fills all 16 FIFO words in 15/16 bpp or 8 FIFO words in 8 bpp.

The following table summarizes how many words can be written to the Blit FIFO.

<table>
<thead>
<tr>
<th>BitBLT Control Register 0 (REG[100h])</th>
<th>8 bpp Word Writes Available</th>
<th>16 bpp Word Writes Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIFO Not Empty Status</td>
<td>FIFO Half Full Status</td>
<td>FIFO Full Status</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
Note
The order of register initialization is irrelevant as long as all relevant registers are pro-
grammed before the BitBLT is initiated.

10.2.3 Color Expand BitBLT With Transparency

This BitBLT operation is virtually identical to the Color Expand BitBLT, except the
background color is completely ignored. All bits set to 1 in the source monochrome bitmap
are color expanded to the foreground color. All bits set to 0 that would be expanded to the
background color in the Color Expand BitBLT are not expanded at all.

Program REG[103h] to 09h instead of 08h. Programming the background color is not
required.

10.2.4 Solid Fill BitBLT

The Solid Fill BitBLT fills a rectangular area of the display buffer with a solid color. This
operation is used to paint large screen areas or to set areas of the display buffer to a given
value.

Example 11: Fill a red 9 x 321 rectangle at the screen coordinates \( x = 100, y = 10 \) us-
using a 640x480 display at a color depth of 16 bpp.

1. Calculate the destination address (upper left corner of the destination rectangle) using
the following formula.

\[
\text{DestinationAddress} = (y \times \text{ScreenStride}) + (x \times \text{BytesPerPixel}) \\
= (10 \times (640 \times 2)) + (100 \times 2) \\
= 13000 \\
= 32C8h
\]

where:
\( \text{BytesPerPixel} = 1 \) for 8 bpp
\( \text{BytesPerPixel} = 2 \) for 15/16 bpp
\( \text{ScreenStride} = \text{DisplayWidthInPixels} \times \text{BytesPerPixel} = 1280 \) for 16 bpp.

Program the BitBLT Destination Start Address Registers. REG[10Ah] is set to 00h,
REG[109h] is set to 32h, and REG[108h] is set to C8h.

2. Program the BitBLT Width Registers to 9 - 1. REG[111h] is set to 00h and
REG[110h] is set to 08h.

3. Program the BitBLT Height Registers to 321 - 1. REG[113h] is set to 01h and
REG[112h] is set to 40h (320 decimal).

4. Program the BitBLT Foreground Color Registers. REG[119h] is set to F8h and
REG[118h] is set to 00h (Full intensity red in 16 bpp is F800h).

5. Program the BitBLT Operation Register to select Solid Fill. REG[103h] is set to 0Ch.
6. Program the BitBLT Color Format Register for 16 bpp operations. REG[101h] is set to 01h.

7. Program the BitBLT Memory Offset Registers to the ScreenStride in WORDS.

\[
\text{BltMemoryOffset} = \frac{\text{ScreenStride}}{2} = 640 = 280h
\]

REG[10Dh] is set to 02h and REG[10Ch] is set to 80h.

8. Program the BitBLT Destination/Source Linear Select bits for a rectangular blit (BitBLT Destination Linear Select = 0, BitBLT Source Linear Select = 0).

Start the blit operation. REG[100h] is set to 80h.

**Note**

The order of register initialization is irrelevant as long as all relevant registers are programmed before the BitBLT is initiated.

### 10.2.5 Move BitBLT in a Positive Direction with ROP

The Move BitBLT moves an area of the display buffer to a different area of the display buffer. This operation has two intended purposes:

- Copying unattended display buffer to display buffer.
- Saving a visible bitmap to off-screen display buffer.

The Move BitBLT may move data from one rectangular area to another, or it may be specified as linear. This allows the temporary saving of a portion of the visible display buffer to an area off-screen. The linear configuration may be applied to the source or destination. Defining the Move BitBLT as linear allows each line of the Move BitBLT area to be placed directly after the previous line, rather than requiring a complete row of address space for each line.

**Note**

When the destination area overlaps the original source area and the destination address is greater then the source address, use the Move BitBLT in Negative Direction with ROP.
Example 12: Copy a 9 x 321 rectangle at the screen coordinates x = 100, y = 10 to screen coordinates x = 200, y = 20 using a 640x480 display at a color depth of 16 bpp.

1. Calculate the source and destination addresses (upper left corners of the source and destination rectangles), using the following formula.

   \[
   \text{SourceAddress} = (y \times \text{ScreenStride}) + (x \times \text{BytesPerPixel})
   \]

   \[
   = (10 \times (640 \times 2)) + (100 \times 2)
   \]

   \[
   = 13000
   \]

   \[
   = 32C8h
   \]

   \[
   \text{DestinationAddress} = (y \times \text{ScreenStride}) + (x \times \text{BytesPerPixel})
   \]

   \[
   = (20 \times (640 \times 2)) + (200 \times 2)
   \]

   \[
   = 26000
   \]

   \[
   = 6590h
   \]

   where:

   - \(\text{BytesPerPixel} = 1\) for 8 bpp
   - \(\text{BytesPerPixel} = 2\) for 15/16 bpp
   - \(\text{ScreenStride} = \text{DisplayWidthInPixels} \times \text{BytesPerPixel} = 1280\) for 16 bpp

   Program the BitBLT Source Start Address Registers. REG[106h] is set to 00h, REG[105h] is set to 32h, and REG[104h] is set to C8h.

   Program the BitBLT Destination Start Address Registers. REG[10Ah] is set to 00h, REG[109h] is set to 65h, and REG[108h] is set to 90h.

2. Program the BitBLT Width Registers to 9 - 1. REG[111h] is set to 00h and REG[110h] is set to 08h.

3. Program the BitBLT Height Registers to 321 - 1. REG[113h] is set to 01h and REG[112h] is set to 40h (320 decimal).

4. Program the BitBLT Operation Register to select the Move BitBLT in Positive Direction with ROP. REG[103h] is set to 02h.
5. Program the BitBLT ROP Code Register to select Destination = Source. REG[102h] is set to 0Ch.

6. Program the BitBLT Color Format Select bit for 16 bpp operations. REG[101h] is set to 01h.

7. Program the BitBLT Memory Offset Registers to the ScreenStride in WORDS.

   BltMemoryOffset = ScreenStride ÷ 2
   = 640
   = 280h

   REG[10Dh] is set to 02h and REG[10Ch] is set to 80h.

8. Program the BitBLT Destination/Source Linear Select bits for a rectangular blit (BitBLT Destination Linear Select = 0, BitBLT Source Linear Select = 0).

   Start the blit operation. REG[100h] is set to 80h.

**Note**

The order of register initialization is irrelevant as long as all relevant registers are programmed before the BitBLT is initiated.

### 10.2.6 Move BitBLT in Negative Direction with ROP

The Move BitBLT in Negative Direction with ROP is very similar to the Move BitBLT in Positive direction and must be used when the source and destination blit areas overlap and the destination address is greater than the source address.

**Note**

For the Move BitBLT in Negative Direction it is necessary to calculate the addresses of the last pixel as opposed to the first pixel. This means calculating the addresses of the lower right corners as opposed to the upper left corners.

**Example 13: Copy a 9 x 321 rectangle at the screen coordinates x = 100, y = 10 to screen coordinates X = 105, Y = 20 using a 640x480 display at a color depth of 16 bpp.**

In the following example, the coordinates of the source and destination rectangles intentionally overlap.

1. Calculate the source and destination addresses (lower right corners of the source and destination rectangles) using the following formula.

   SourceAddress
   = ((y + Height - 1) × ScreenStride) + ((x + Width - 1) × BytesPerPixel)
   = ((10 + 321 - 1) × (640 × 2)) + ((100 + 9 - 1) × 2)
   = 422616
   = 672D8h
DestinationAddress
= ((Y + Height - 1) \times ScreenStride) + ((X + Width - 1) \times BytesPerPixel)
= ((20 + 321 - 1) \times (640 \times 2)) + ((105 + 9 - 1) \times 2)
= 435426
= 6A4E2h

where:
BytesPerPixel = 1 for 8 bpp
BytesPerPixel = 2 for 15/16 bpp
ScreenStride = DisplayWidthInPixels \times BytesPerPixel = 1280 for 16 bpp

Program the BitBLT Source Start Address Registers. REG[106h] is set to 06h, REG[105h] is set to 72h, and REG[104h] is set to D8h.

Program the BitBLT Destination Start Address Registers. REG[10Ah] is set to 06h, REG[109h] is set to A4h, and REG[108h] is set to E2h.

2. Program the BitBLT Width Registers to 9 - 1. REG[111h] is set to 00h and REG[110h] is set to 08h.

3. Program the BitBLT Height Registers to 321 - 1. REG[113h] is set to 01h and REG[112h] is set to 40h (320 decimal).

4. Program the BitBLT Operation Register to select the Move Blit in Negative Direction with ROP. REG[103] is set to 03h.

5. Program the BitBLT ROP Code Register to select Destination = Source. REG[102h] is set to 0Ch.

6. Program the BitBLT Color Format Select bit for 16 bpp operations. REG[101h] is set to 01h.

7. Program the BitBLT Memory Offset Registers to the ScreenStride in WORDS.

    BltMemoryOffset = ScreenStride \div 2
    = 640
    = 280h

REG[10Dh] is set to 02h and REG[10Ch] is set to 80h.

8. Program the BitBLT Destination/Source Linear Select bits for a rectangular blit (BitBLT Destination Linear Select = 0, BitBLT Source Linear Select = 0).

    Start the blit operation. REG[100h] is set to 80h.

**Note**
The order of register initialization is irrelevant as long as all relevant registers are programmed before the BitBLT is initiated.
10.2.7 Transparent Write Blit

The Transparent Write Blit increases the speed of transferring data from system memory to the display buffer. Once the Transparent Write Blit begins, the blit engine remains active until all pixels have been written.

The Transparent Write Blit updates a specified area of the display buffer with data supplied by the CPU. This blit is typically used to copy a bitmap image from system memory to the display buffer with one color marked as transparent. Any pixel of the transparent color is not transferred. This allows fast display of non-rectangular images. For example, consider a source bitmap having a red circle on a blue background. By selecting the blue color as the transparent color and using the Transparent Write Blit on the whole rectangle, the effect is a blit of the red circle only. The Transparent Write Blit supports both Destination Linear and Destination Rectangular modes.

This Transparent Write Blit requires the CPU to provide data. The blit engine expects to receive a certain number of WORDS. For 15/16 bpp color depths, the number of WORDS is the same as the number of pixels due to the fact that each pixel is one WORD wide. The number of WORD writes the blit engine expects is calculated using the following formula.

\[
\text{nWORDS} = \frac{\text{nPixels}}{\text{Blit Width}}
\]

For 8 bpp color depths, the formula must take into consideration that the blit engine accepts only WORD accesses and each pixel is one BYTE. The blit engine needs to know whether the first pixel of a line is stored in the low byte or high byte. This is determined by bit 0 of the Source Start Address Register 0 (REG[104h]). If the Source Phase is 1 (bit 0 of the Source Start Address Register 0 is set), the first pixel of each line is in the high byte of the WORD and the contents of the low byte are ignored. If the Source Phase is 0, the first pixel is in the low byte and the second pixel is in the high byte. Depending on the Source Phase and the Blit Width, the last WORD in each line may contain only one pixel. It is always in the low byte if more than one WORD per line is required. The number of WORD reads the blit engine expects for 8 bpp color depths is shown in the following formula.

\[
\text{nWORDS} = \left(\frac{\text{Blit Width} + 1 + \text{SourcePhase}}{2}\right) \times \text{BlitHeight}
\]

Note

The blit engine counts WORD writes in the blit address space. This does not imply only 16-bit CPU instructions are acceptable. If a system is able to separate one DWORD write into two WORD writes, then 32-bit CPU instructions are acceptable. Otherwise, two back to back 16-bit CPU instructions are required.

Example 14: Write 100 x 20 pixels at the screen coordinates x = 25, y = 38 using a 640x480 display at a color depth of 8 bpp. Transparent color is high intensity blue (assumes LUT Index 124).

1. Calculate the destination address (upper left corner of the screen blit rectangle), using the formula:
DestinationAddress = (y \times \text{ScreenStride}) + (x \times \text{BytesPerPixel})
= (38 \times 640) + (25 \times 1)
= 24345
= 5F19h

where:
BytesPerPixel = 1 for 8 bpp
BytesPerPixel = 2 for 15/16 bpp
ScreenStride = \text{DisplayWidthInPixels} \times \text{BytesPerPixel} = 640 for 8 bpp

Program the BitBLT Destination Start Address Registers. REG[10Ah] is set to 00h, REG[109h] is set to 5Fh, and REG[108h] is set to 19h.

2. Program the BitBLT Width Registers to 100 - 1. REG[111h] is set to 00h and REG[110h] is set to 63h (99 decimal).

3. Program the BitBLT Height Registers to 20 - 1. REG[113h] is set to 00h and REG[112h] is set to 13h (19 decimal).

4. Program the Source Phase in the BitBLT Source Start Address Register. In this example, the data is WORD aligned, so the source phase is 0. REG[104h] is set to 00h.

5. Program the BitBLT Operation Register to select Transparent Write Blit. REG[103h] is set to 04h.

6. Program the BitBLT Background Color Registers to select transparent color. REG[114h] is set to 7Ch (124 decimal).

Note that for 15/16 bpp color depths, REG[115h] and REG[114h] are both required and programmed directly with the value of the transparent background color.

7. Program the BitBLT Color Format Select bit for 8 bpp operations. REG[101h] is set to 00h.

8. Program the BitBLT Memory Offset Registers to the ScreenStride in WORDS.

\[
\text{BltMemoryOffset} = \frac{\text{ScreenStride}}{2}
= \frac{640}{2}
= 320
= 140h
\]

REG[10Dh] is set to 01h and REG[10Ch] is set to 40h.

9. Calculate the number of WORDS the blit engine expects to receive.

\[
n\text{WORDS} = \frac{(\text{BlitWidth} + 1 + \text{SourcePhase})}{2} \times \text{BlitHeight}
= \frac{(100 + 1 + 0)}{2} \times 20
= 1000
= 3E8h\]
10. Program the BitBLT Destination/Source Linear Select bits for a rectangular blit (BitBLT Destination Linear Select = 0, BitBLT Source Linear Select = 0).

Start the blit operation **and wait for the blit engine to start**. REG[100h] is set to 80h, then wait until REG[100h] bit 7 returns a 1.

11. Prior to writing all nWORDS to the Blit FIFO, confirm the Blit FIFO is not full (REG[100h] bit 4 returns a 0). If the BitBLT FIFO Not Empty Status returns a 0 (the FIFO is empty), write up to 16 WORDS. If the BitBLT FIFO Not Empty Status returns a 0 and the BitBLT FIFO Half Full Status returns a 0 then you can write up to 8 WORDS. If the BitBLT FIFO Full Status returns a 1, do not write to the BitBLT FIFO until it returns a 0.

The following table summarizes how many words can be written to the Blit FIFO.

<table>
<thead>
<tr>
<th>BitBLT Control Register 0 (REG[100h])</th>
<th>Word Writes Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIFO Not Empty Status</td>
<td>FIFO Half Full Status</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

**Note**

The order of register initialization is irrelevant as long as all relevant registers are programmed before the BitBLT is initiated.

### 10.2.8 Transparent Move BitBLT in Positive Direction

The Transparent Move BitBLT in Positive Direction moves an area of the display buffer to a different area of the display buffer. It allows for selection of a transparent color which is not copied during the blit. This allows fast display of non-rectangular images. For example, consider a source bitmap having a red circle on a blue background. By selecting the blue color as the transparent color and using the Transparent Move Blit on the whole rectangle, the effect is a blit of the red circle only.

The Transparent Move BitBLT may move data from one rectangular area to another, or it may be specified as linear. The linear configuration may be applied to the source or destination. Defining the Move BitBLT as linear allows each line of the Move BitBLT area to be placed directly after the previous line, rather than requiring a complete row of address space for each line.

**Note**

The Transparent Move BitBLT is supported only in a positive direction.
Example 15: Copy a 9 x 321 rectangle at the screen coordinates x = 100, y = 10 to screen coordinates X = 200, Y = 20 using a 640x480 display at a color depth of 16 bpp. Transparent color is blue.

1. Calculate the source and destination addresses (upper left corners of the source and destination rectangles), using the formula:

\[
\text{SourceAddress} = (y \times \text{ScreenStride}) + (x \times \text{BytesPerPixel}) \\
= (10 \times (640 \times 2)) + (100 \times 2) \\
= 13000 \\
= 32C8h
\]

\[
\text{DestinationAddress} = (Y \times \text{ScreenStride}) + (X \times \text{BytesPerPixel}) \\
= (20 \times (640 \times 2)) + (200 \times 2) \\
= 26000 \\
= 6590h
\]

where:

- \( \text{BytesPerPixel} = 1 \) for 8 bpp
- \( \text{BytesPerPixel} = 2 \) for 15/16 bpp
- \( \text{ScreenStride} = \text{DisplayWidthInPixels} \times \text{BytesPerPixel} = 1280 \) for 16 bpp

Program the BitBLT Source Start Address Registers. REG[106h] is set to 00h, REG[105h] is set to 32h, and REG[104h] is set to C8h.

Program the BitBLT Destination Start Address Registers. REG[10Ah] is set to 00h, REG[109h] is set to 65h, and REG[108h] is set to 90h.

2. Program the BitBLT Width Registers to 9 - 1. REG[111h] is set to 00h and REG[110h] is set to 08h.

3. Program the BitBLT Height Registers to 321 - 1. REG[113h] is set to 01h and REG[112h] is set to 40h (320 decimal).

4. Program the BitBLT Operation Register to select the Transparent Move Blit in Positive Direction. REG[103h] is set to 05h.

5. Program the BitBLT Background Color Registers to select blue as the transparent color. REG[115h] is set to 00h and REG[114h] is set to 1Fh (Full intensity blue in 16 bpp is 001Fh).

6. Program the BitBLT Color Format Register to select 16 bpp operations. REG[101h] is set to 01h.

7. Program the BitBLT Memory Offset Registers to the ScreenStride in WORDS.

\[
\text{BltMemoryOffset} = \frac{\text{ScreenStride}}{2} \\
= 640 \\
= 280h
\]

REG[10Dh] is set to 02h and REG[10Ch] is set to 80h.
8. Program the BitBLT Destination/Source Linear Select bits for a rectangular blit (BitBLT Destination Linear Select = 0, BitBLT Source Linear Select = 0).

Start the blit operation. REG[100h] is set to 80h.

**Note**
The order of register initialization is irrelevant as long as all relevant registers are programmed before the BitBLT is initiated.

### 10.2.9 Pattern Fill BitBLT with ROP

The Pattern Fill BitBLT with ROP fills a specified rectangular area of the display buffer with a pattern. The fill pattern is an array of pixels stored in off-screen display buffer. The fill pattern is limited to an eight by eight pixel array and must be loaded to off-screen memory prior to the BitBLT starting. The pattern can be logically combined with the destination using all 16 ROP codes, but typically the copy pattern ROP is used (ROP code 0Ch).

The pattern itself must be stored in a consecutive array of pixels. As a pattern is defined to be eight pixels square, this results in 64 consecutive bytes for 8 bpp color depths and 128 bytes for 15/16 bpp color depths. For 8 bpp color depths the pattern must begin on a 64 byte boundary, for 15/16 bpp color depths the pattern must begin on a 128 byte boundary.

To fill an area using the pattern BitBLT, the blit engine requires the location of the pattern, the destination rectangle position and size, and the ROP code. The blit engine also needs to know which pixel from the pattern is the first pixel in the destination rectangle (the pattern start phase). This allows seamless redrawing of any part of the screen using the pattern fill.

**Example 16:** Fill a 100 x 250 rectangle at the screen coordinates x = 10, y = 20 with the pattern in off-screen memory at offset 10000h using a 640x480 display at a color depth of 8 bpp. The first pixel (upper left corner) of the rectangle is the pattern pixel at x = 3, y = 4.

1. Calculate the destination address (upper left corner of the destination rectangle), using the formula:

   \[
   \text{DestinationAddress} = (y \times \text{ScreenStride}) + (x \times \text{BytesPerPixel})
   \]

   \[
   = (20 \times 640) + (10 \times 1)
   \]

   \[
   = 12810
   \]

   \[
   = 320Ah
   \]

   where:

   - BytesPerPixel = 1 for 8 bpp
   - BytesPerPixel = 2 for 15/16 bpp
   - ScreenStride = DisplayWidthInPixels \times BytesPerPixel = 640 for 8 bpp

   Program the BitBLT Destination Start Address Registers. REG[10Ah] is set to 00h, REG[109h] is set to 32h, and REG[108h] is set to 0Ah.

2. Calculate the source address. This is the address of the pixel in the pattern that is the origin of the destination fill area. The pattern begins at offset 1M, but the first pattern pixel is at x = 3, y = 4. Therefore, an offset within the pattern itself must be calculated.
SourceAddress
= PatternOffset + StartPatternY \times 8 \times \text{BytesPerPixel} + \text{StartPatternX} \times \text{BytesPerPixel}
= 1\text{M} + (4 \times 8 \times 1) + (3 \times 1)
= 1\text{M} + 35
= 1048611
= 100023\text{h}

where:
\text{BytesPerPixel} = 1 \text{ for 8 bpp }
\text{BytesPerPixel} = 2 \text{ for 15/16 bpp }

Program the BitBLT Source Start Address Registers. REG[106h] is set to 10h, REG[105h] is set to 00h, and REG[104h] is set 23h.

3. Program the BitBLT Width Registers to 100 - 1. REG[111h] is set to 00h, REG[110h] is set to 63h (99 decimal).

4. Program the BitBLT Height Registers to 250-1. REG[113h] is set to 00h, and REG[112h] is set to F9h (249 decimal).

5. Program the BitBLT Operation Register to select the Pattern Fill with ROP. REG[103h] is set to 06h.

6. Program the BitBLT ROP Code Register to select Destination = Source. REG[102h] is set to 0Ch.

7. Program the BitBLT Color Format Select bit for 8 bpp operations. REG[101h] is set to 00h.

8. Program the BitBLT Memory Offset Registers to the ScreenStride in WORDS.

\[
\text{BltMemoryOffset} = \frac{\text{ScreenStride}}{2}
\]
\[
= 640 \div 2
\]
\[
= 320
\]
\[
= 140\text{h}
\]

REG[10Dh] is set to 01h and REG[10Ch] is set to 40h.

9. Program the BitBLT Destination/Source Linear Select bits for a rectangular blit (BitBLT Destination Linear Select = 0, BitBLT Source Linear Select = 0).

Start the blit operation. REG[100h] is set to 80h.

**Note**
The order of register initialization is irrelevant as long as all relevant registers are programmed before the BitBLT is initiated.
10.2.10 Pattern Fill BitBLT with Transparency

The Pattern Fill BitBLT with Transparency fills a specified rectangular area of the display buffer with a pattern. When a transparent color is selected, pattern pixels of the transparent color will not get copied, allowing creation of hatched patterns. The fill pattern is an eight by eight array of pixels stored in off-screen display buffer. The fill pattern must be loaded to off-screen display buffer prior to the BitBLT starting.

The pattern itself must be stored in a consecutive array of pixels. As a pattern is defined to be eight pixels square, this results in 64 consecutive bytes for 8 bpp color depths and 128 bytes for 15/16 bpp color depths. For 8 bpp color depths the pattern must begin on a 64 byte boundary, for 15/16 bpp color depths the pattern must begin on a 128 byte boundary.

To fill an area using the Pattern Fill BitBLT with Transparency, the blit engine requires the location of the pattern, the destination rectangle position and size, and the transparency color. The blit engine also needs to know which pixel from the pattern is the first pixel in the destination rectangle (the pattern start phase). This allows seamless redrawing of any part of the screen using the pattern fill.

Example 17: Fill a 100 x 250 rectangle at the screen coordinates x = 10, y = 20 with the pattern in off-screen memory at offset 10000h using a 640x480 display at a color depth of 8 bpp. The first pixel (upper left corner) of the rectangle is the pattern pixel at x = 3, y = 4. Transparent color is blue (assumes LUT index 1).

1. Calculate the destination address (upper left corner of destination rectangle), using the formula:

\[
\text{DestinationAddress} = (y \times \text{ScreenStride}) + (x \times \text{BytesPerPixel})
\]

\[
= (20 \times 640) + (10 \times 1)
\]

\[
= 12810
\]

\[
= 320Ah
\]

where:

- BytesPerPixel = 1 for 8 bpp
- BytesPerPixel = 2 for 15/16 bpp
- ScreenStride = DisplayWidthInPixels × BytesPerPixel = 640 for 8 bpp

Program the BitBLT Destination Start Address Registers. REG[10Ah] is set to 00h, REG[109h] is set to 32h, and REG[108h] is set to 0Ah.

2. Calculate the source address. This is the address of the pixel in the pattern that is the origin of the destination fill area. The pattern begins at offset 1M, but the first pattern pixel is at x = 3, y = 4. Therefore, an offset within the pattern itself must be calculated.

\[
\text{SourceAddress} = \text{PatternOffset} + \text{StartPatternY} \times 8 \times \text{BytesPerPixel} + \text{StartPatternX} \times \text{BytesPerPixel}
\]

\[
= 1M + (4 \times 8 \times 1) + (3 \times 1)
\]

\[
= 1M + 35
\]

\[
= 1048611
\]

\[
= 100023h
\]
where:
BytesPerPixel = 1 for 8 bpp
BytesPerPixel = 2 for 15/16 bpp

Program the BitBLT Source Start Address Registers. REG[106h] is set to 10h, REG[105h] is set to 00h, and REG[104h] is set 23h.

3. Program the BitBLT Width Registers to 100 - 1. REG[111h] is set to 00h and REG[110h] is set to 63h (99 decimal).

4. Program the BitBLT Height Registers to 250-1. REG[113h] is set to 00h, and REG[112h] is set to F9h (249 decimal).

5. Program the BitBLT Operation Register to select the Pattern Fill BitBLT with Transparency. REG[103h] is set to 07h.

6. Program the BitBLT Background Color Registers to select transparent color. This example uses blue (LUT index 1) as the transparent color. REG[114h] is set to 01h.

Note that for 15/16 bpp color depths, REG[115h] and REG[114h] are both required and programmed directly with the value of the transparent background color. For example, for full intensity green to be the transparent color in 16 bpp, REG[115h] is set to 07h and REG[114h] is set to E0h.

7. Program the BitBLT Color Format Select bit for 8 bpp operations. REG[101h] is set to 00h.

8. Program the BitBLT Memory Offset Registers to the ScreenStride in WORDS.

\[
\text{BltMemoryOffset} = \text{ScreenStride} \div 2
\]
\[
= 640 \div 2
\]
\[
= 320
\]
\[
= 140h
\]

REG[10Dh] is set to 01h and REG[10Ch] is set to 40h.

9. Program the BitBLT Destination/Source Linear Select bits for a rectangular blit (BitBLT Destination Linear Select = 0, BitBLT Source Linear Select = 0).

Start the blit operation. REG[100h] is set to 80h.

Note
The order of register initialization is irrelevant as long as all relevant registers are programmed before the BitBLT is initiated.

10.2.11 Move BitBLT with Color Expansion

The Move BitBLT with Color Expansion takes a monochrome bitmap as the source and color expands it into the destination. Color expansion moves all bits in the monochrome source to pixels in the destination. All bits in the source set to one are expanded into destination pixels of the selected foreground color. All bits in the source set to zero are expanded into pixels of the selected background color.
The Move BitBLT with Color Expansion is used to accelerate text drawing on the screen. A monochrome bitmap of a font in off-screen memory occupies very little space and takes advantage of the hardware acceleration. Since the foreground and background colors are programmable, text of any color can be created.

The Move BitBLT with Color Expansion may move data from one rectangular area to another, or it may be specified as linear. The linear configuration may be applied to the source or destination. Defining the Move BitBLT as linear allows each line of the Move BitBLT area to be placed directly after the previous line, rather than requiring a complete row of address space for each line.

**Note**

The BitBLT ROP Code/Color Expansion Register must be programmed to value 07h because in the first word in a line color expansion is started with the most significant bit of the low byte.

*Example 18: Color expand a 9 x 16 rectangle using the pattern in off-screen memory at 10 0000h and move it to the screen coordinates x = 200, y = 20. Assume a 640x480 display at a color depth of 16 bpp, Foreground color of black, and background color of white.*

1. Calculate the destination and source addresses (upper left corner of the destination and source rectangles), using the formula.

   DestinationAddress = (y × ScreenStride) + (x × BytesPerPixel)
                      = (20 × (640 × 2)) + (200 × 2)
                      = 26000
                      = 6590h

   where:
   
   BytesPerPixel = 1 for 8 bpp
   BytesPerPixel = 2 for 15/16 bpp
   ScreenStride = DisplayWidthInPixels × BytesPerPixel = 1280 for 16 bpp
   
   SourceAddress = 1M
   = 100000h

   Program the BitBLT Destination Start Address Registers. REG[10Ah] is set to 00h, REG[109h] is set to 65h, and REG[108h] is set to 90h.

   Program the BitBLT Source Start Address Registers. REG[106h] is set to 10h, REG[105h] is set to 00h, and REG[104h] is set to 00h.

2. Program the BitBLT Width Registers to 9 - 1. REG[111h] is set to 00h and REG[110h] is set to 08h.

3. Program the BitBLT Height Registers to 16 - 1. REG[113h] is set to 00h and REG[112h] is set to 0Fh.

4. **Program the BitBLT ROP Code/Color Expansion Register. REG[102h] is set to 07h.**
5. Program the BitBLT Operation Register to select the Move Blit with Color Expansion. REG[103h] is set to 0Bh.

6. Program the BitBLT Foreground Color Register to select black (in 16 bpp black = 0000h). REG[119h] is set to 00h and REG[118h] is set to 00h.

7. Program the BitBLT Background Color Register to select white (in 16 bpp white = FFFFh). REG[115h] is set to FFh and REG[114h] is set to FFh.

8. Program the BitBLT Color Format Select bit for 16 bpp operations. REG[101h] is set to 01h.

9. Program the BitBLT Memory Offset Registers to the ScreenStride in WORDS.
   
   \[
   \text{BltMemoryOffset} = \frac{\text{ScreenStride}}{2} = 640 = 280h
   \]

   REG[10Dh] is set to 02h and REG[10Ch] is set to 80h.

10. Program the BitBLT Destination/Source Linear Select bits for a rectangular blit (BitBLT Destination Linear Select = 0, BitBLT Source Linear Select = 0).

    Start the blit operation. REG[100h] is set to 80h.

**Note**

The order of register initialization is irrelevant as long as all relevant registers are programmed before the BitBLT is initiated.

### 10.2.12 Transparent Move Blit with Color Expansion

The Transparent Move Blit with Color Expansion is virtually identical to the Move Blit with Color Expansion. The background color is ignored and bits in the monochrome source bitmap set to 0 are not color expanded.

### 10.2.13 Read Blit

This Read Blit increases the speed of transferring data from the display buffer to system memory. This blit complements the Write Blit and is typically used to save a part of the display buffer to the system memory. Once the Read Blit begins, the blit engine remains active until all the pixels have been read.

The blit engine requires the address to copy from and the size of the area to copy (width x height). The blit engine expects to read a certain number of words. For 15/16 bpp color depths, the number of words is the same as the number of pixels due to the fact that each pixel is one WORD wide. The number of WORD reads the blit engine expects is calculated using the following formula.

\[
\text{nWORDS} = \frac{\text{nPixels}}{\text{Blit Width} \times \text{Blit Height}}
\]
For 8 bpp color depths, the formula must take into consideration that the blit engine accepts only WORD accesses and each pixel is one BYTE. The blit engine needs to know whether the first pixel of each line is stored in the low byte or high byte. This is determined by bit 0 of the Destination Start Address Register 0 (REG[108h]). If the Destination Phase is 1 (bit 0 of the Destination Start Address Register 0 is set), the first pixel of each line is placed in the high byte of the WORD and the contents of the low byte is undefined. If the Destination Phase is 0, the first pixel is placed in the low byte and the second pixel is placed in the high byte. Depending on the Destination Phase and the Blit Width, the last WORD in each line may contain only one pixel. It is always in the low byte if more than one WORD per line is required. The number of WORD reads the blit engine expects for 8 bpp color depths is shown in the following formula.

\[ n\text{WORDS} = \left(\frac{(\text{BlitWidth} + 1 + \text{DestinationPhase})}{2}\right) \times \text{BlitHeight} \]

**Example 19: Read 100 x 20 pixels at the screen coordinates x = 25, y = 38 and save to system memory. Assume a display of 640x480 at a color depth of 8 bpp.**

1. Calculate the source address (upper left corner of the screen blit rectangle), using the formula.

   \[
   \text{SourceAddress} = (y \times \text{ScreenStride}) + (x \times \text{BytesPerPixel})
   \]

   \[
   = (38 \times 640) + (25 \times 1)
   \]

   \[
   = 24345
   \]

   \[
   = 5F19h
   \]

   where:

   - \( \text{BytesPerPixel} = 1 \) for 8 bpp
   - \( \text{BytesPerPixel} = 2 \) for 15/16 bpp
   - \( \text{ScreenStride} = \text{DisplayWidthInPixels} \times \text{BytesPerPixels} = 640 \) for 8 bpp

   Program the BitBLT Source Start Address Registers. REG[106h] is set to 00h, REG[105h] is set to 5Fh, and REG[104h] is set to 19h.

2. Program the BitBLT Width Registers to 100 - 1. REG[111h] is set to 00h and REG[110h] is set to 63h (99 decimal).

3. Program the BitBLT Height Registers to 20 - 1. REG[113h] is set to 00h and REG[112h] is set to 13h (19 decimal).

4. Program the Destination Phase in the BitBLT Destination Start Address Register. In this example, the data is WORD aligned, so the destination phase is 0. REG[108h] is set to 0.

5. Program the BitBLT Operation to select the Read Blit. REG[103h] is set to 01h.

6. Program the BitBLT Color Format Select bit for 8 bpp operations. REG[101h] is set to 00h.

7. Program the BitBLT Memory Offset Registers to the ScreenStride in WORDS.
BltMemoryOffset = ScreenStride ÷ 2
= 640 ÷ 2
= 320
= 140h

REG[10Dh] is set to 01h and REG[10Ch] is set to 40h.

8. Calculate the number of WORDS the blit engine expects to receive.

\[
nWORDS = \left(\frac{(\text{BlitWidth} + 1 + \text{DestinationPhase})}{2}\right) \times \text{BlitHeight}
\]

\[
= \left(\frac{100 + 1 + 0}{2}\right) \times 20
\]

\[
= 1000
\]

\[
= 3E8h
\]

9. Program the BitBLT Destination/Source Linear Select bits for a rectangular blit (BitBLT Destination Linear Select = 0, BitBLT Source Linear Select = 0).

Start the blit operation and wait for the blit engine to start. REG[100h] is set to 80h, then wait until REG[100h] bit 7 returns a 1.

10. Prior to reading all nWORDS from the Blit FIFO, confirm the Blit FIFO is not empty (REG[100h] bit 4 returns a 1). If the BitBLT FIFO Not Empty Status returns a 1 and the BitBLT FIFO Half Full Status returns a 0 then you can read up to 8 WORDS. If the BitBLT FIFO Full Status returns a 1, read up to 16 WORDS. If the BitBLT FIFO Not Empty Status returns a 0 (the FIFO is empty), do not read from the BitBLT FIFO until it returns a 1.

The following table summarizes how many words can be read from the Blit FIFO.

<table>
<thead>
<tr>
<th>BitBLT Control Register 0 (REG[100h])</th>
<th>Word Reads Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIFO Not Empty Status</td>
<td>FIFO Half Full Status</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Note
The order of register initialization is irrelevant as long as all relevant registers are programmed before the BitBLT is initiated.

10.3 S1D13506 BitBLT Synchronization

A BitBLT operation can only be started if the blit engine is not busy servicing another blit. Before a new BitBLT operation is started, software must confirm the BitBLT Active Status bit (REG[100h] bit 7) returns a 0. Software can either test this bit after each BitBLT operation, or before each BitBLT operation.

Testing the BitBLT Status After
Testing the BitBLT Active Status after starting a new BitBLT is simpler and less prone to errors.

To test after each BitBLT operation, perform the following.

1. Program and start the blit engine.

2. Wait for the current BitBLT operation to finish -- Poll the BitBLT Active Status bit (REG[100h] bit) until it returns a 0.

3. Continue the program.
Testing the BitBLT Status Before

Testing the BitBLT Active Status before starting a new BitBLT results in better performance, as both CPU and blit engine can be running at the same time. This is most useful for BitBLTs that are self completing (once started they don’t require any CPU assistance). While the blit engine is busy, the CPU can do other tasks. To test before each BitBLT operation, perform the following.

1. Wait for the current BitBLT operation to finish -- Poll the BitBLT Active Status bit (REG[100h] bit 7) until it returns a 0.
2. Program and start the new BitBLT operation.
3. Continue the program (CPU and blit engine work independently).

However, this approach can pose problems if the CPU writes a pixel while the blit engine is running a blit. If the CPU writes the pixel before the BitBLT finishes, the pixel may be overwritten by the blit. To avoid this scenario, always assure no BitBLT is in progress before accessing the display buffer with the CPU, or don’t use the CPU to access display buffer at all.

10.4 S1D13506 BitBLT Known Limitations

The S1D13506 blit engine has the following limitations.

- BitBLT Width must be greater than 0.
- BitBLT Height must be greater than 0.
- The blit engine is not SwivelView aware. If BitBLTs are used when SwivelView is enabled, the coordinates and vertices are swapped. It may be possible to recalculate these coordinates and vertices allowing use of some of the BitBLT functions. However the coordinate transformations required may nullify the benefits of the BitBLT.
- The Pattern Fill with ROP (0Ch or 03h) and Transparent Pattern Fill are designed such that the BitBLT Width must be > 1 for 15/16 bpp color depths and > 2 for 8 bpp.

10.5 Sample Code

Sample code demonstrating how to program the S1D13506 BitBLT engine is provided in the file **13506BLT.ZIP**. This file is available on the internet at www.eea.epson.com.
11 CRT/TV Considerations

The S1D13506 is capable of driving an LCD panel, CRT display, or a TV monitor. However, only an LCD panel and CRT or an LCD panel and TV can be driven simultaneously. It is not possible to drive both a CRT and TV at the same time.

The horizontal and vertical timing requirements of LCD panels allows for a wide timing variance. In comparison, a CRT display has very strict timing requirements with even a very small timing variance degrading the displayed image. TV monitors require timings based on the NTSC or PAL specifications.

The utility 13506CFG.EXE can be used to generate a header file containing the register values required for CRT/TV or LCD panel timings. For further information on 13506CFG.EXE, see the 13506CFG Users Manual, document number X25B-B-001-xx.

11.1 CRT Considerations

CRT timings are based on the VESA Monitor Timing Specifications. The VESA specification details all the parameters of the display and non-display times, as well as the input clock required to meet the times. **Failing to use correct timings can result in an unsynchronized image on a particular monitor, which can permanently damage the monitor.** Virtually all VGA monitors sync if VESA timings are used.

For more information on VESA timings, contact the Video Electronics Standards Association on the internet at www.vesa.org.

11.1.1 Generating CRT timings with 13506CFG

13506CFG.EXE will generate correct VESA timings for 640x480 and 800x600 if provided the correct VESA input clock. The following timings can be generated:

- 640x480 @ 60Hz (Input Clock = 25.175 MHz)
- 640x480 @ 72Hz  (Input Clock = 31.500 MHz)
- 640x480 @ 75Hz  (Input Clock = 31.500 MHz)
- 640x480 @ 85 Hz (Input Clock = 36.000 MHz)
- 800x600 @ 56 Hz (Input Clock = 36.000 MHz)
- 800x600 @ 60 Hz (Input Clock = 40.000 MHz)

11.1.2 DAC Output Level Selection

When the CRT is active, the DAC Output Level Select bit (REG[05Bh] bit 3) can be used to double values output to the DAC. This would normally result in very bright colors on the display, but if IREF is reduced at the same time the display will remain at its intended brightness and power consumption is reduced.
11.1.3 Examples

Example 20: Enable the CRT display. Assume the CRT timing registers are already programmed.

1. Confirm the TV PAL/NTSC Output Select bit is clear. REG[05Bh] bit 0 is set to 0.
2. Confirm the CRT and TV displays are disabled. REG[1FCh] bits 2-1 are set to 0.
3. Enable the CRT. REG[1FCh] is set to 1.

Sample code demonstrating how to enable the CRT display is provided in the file 56_CRT.c. This file is available on the internet at www.eea.epson.com.

11.2 TV Considerations

TV timings are based on either the NTSC or PAL specifications. The TV display can be output in either composite video or S-video format.

11.2.1 NTSC Timings

NTSC timings require a 14.318 MHz input clock. With the correct input clock the following resolutions are supported.

- 640x480
- 696x436
- 752x484

11.2.2 PAL Timings

PAL timings require a 17.734 MHz input clock. With the correct input clock the following resolutions are supported.

- 640x480
- 800x572
- 856x518
- 920x572
11.2.3 TV Filters

The S1D13506 is designed with three filters which improve TV picture quality.

- Flicker Filter.
- Chrominance Filter.
- Luminance Filter.

Each filter is independent and can be enabled/disabled separately. The TV picture quality varies depending on the actual picture displayed (static image, moving image, number of colors etc.) and may be improved using the filters.

Flicker Filter

The Flicker Filter is controlled by the Display Mode Select bits (REG[1FCh] bits 2-0). It reduces the “flickering” effect seen on interlaced displays caused by sharp vertical image transitions that occur over one line (e.g. one pixel high lines, edges of window boxes, etc.). The Flicker Filter may be used to for both composite video and S-video formats.

Note

The CRT/TV PCLK 2X Enable bit (REG[018h] bit 7) must be set to 1 when the Flicker Filter is enabled.

Chrominance Filter

The Chrominance Filter is controlled by the TV Chrominance Filter Enable bit (REG[05Bh] bit 5). It adjusts the color of the TV, reducing the “ragged edges” seen at the boundaries between sharp color transitions. The Chrominance Filter may improve the TV picture quality when in composite video format.

Luminance Filter

The Luminance Filter is controlled by the TV Luminance Filter Enable bit (REG[05Bh] bit 4). It adjusts the brightness of the TV, reducing the “rainbow-like” colors at the boundaries between sharp brightness transitions. The Luminance Filter may improve the TV picture quality when in composite video format.

For further information on the TV filters, see the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx.

11.2.4 Examples

Example 21: Enable the TV display and set the Flicker Filter. Assume the TV timing registers are already programmed.

1. Enable the TV with Flicker Filter enabled. REG[1FCh] is set to 06h.

2. Enable the CRT/TV PCLK 2X bit (REG[018h] bit 7). REG[018h] bit 7 is set to 1b.
Sample code demonstrating how to enable the TV display is provided in the file 156_TV.c. This file is available on the internet at www.eea.epson.com.

11.3 Simultaneous Display

The S1D13506 supports simultaneous display of an LCD panel and CRT or an LCD panel and TV. Both display images are completely independent. Each display can show separate areas of the display buffer and display different color depths. There are separate Look-Up Tables and Hardware Cursors/Ink Layers for both the LCD and CRT/TV. If desired, the LUTs for the LCD and CRT/TV may be written to simultaneously (REG[1E0h] bit 0 = 0).

Note
Not all combinations of panel and CRT/TV display resolutions are possible. For further information, see the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx.
12 MediaPlug

The S1D13506 is designed with support for MediaPlug. MediaPlug is a digital interface supporting the Winnov Videum camera. The Videum camera supports simultaneous video and audio capture of streaming (real-time) and still images. It also supports streaming live video at speeds near 30 frames per second on fast host systems (i.e. Pentium-2 300MHz or faster).

12.1 Programming

MediaPlug and the Winnov Videum camera are a proprietary design of Winnov. Due to the complexity of the digital interface, all software and drivers for the camera are provided by Winnov.

The MediaPlug interface on the S1D13506 must be enabled to function correctly. To enable the MediaPlug interface, MD13 and MD14 must be high (1) on the rising edge of RESET#. When the MediaPlug interface is enabled, **GPIO2 is controlled by the MediaPlug LCMD register, and the GPIO2 bits in both REG[004h] and REG[008h] have no effect.** Also when the MediaPlug interface is enabled, the camera power (VMPEPWR) is controlled by MA11/GPIO2 pin.

The MediaPlug LCMD 16-bit register REG[1000h] contains status bits which can be read by software. For further information on these status bits, see the *S1D13506 Hardware Functional Specification*, document number X25B-A-001-xx.

The MediaPlug IC Revision bits (REG[1000h] bits 11-8) contain the revision of the interface. The 16-bit value read from REG[1000h] should be masked with 0F00h and compared with 0300h (the current revision of the interface).

The MediaPlug Cable Detected Status bit (REG[1000h] bit 7) determines if a camera is connected to the MediaPlug interface. When this bit returns a 0, a camera is connected. When this bit returns a 1, a camera is not connected.

The MediaPlug Power Enable to Remote bit (REG[1000h], bit 1) controls the power to the remote camera. GPIO2 is controlled by this bit when the MediaPlug interface is enabled. Therefore, this bit must be used instead of the GPIO2 control bits in REG[004h] and REG[008h] when programming the external ICD2061A clock chip used on the S5U13506B00x evaluation boards. Writing this bit is necessary only when software needs to control the MA11/GPIO2 pin.

12.2 Considerations

Software can determine if the MediaPlug interface is enabled or disabled by reading the MD Configuration Readback Register (REG[00Dh]) and masking the data with 60h. If the masked result equals 60h, the MediaPlug Interface is enabled.
When the MediaPlug interface is enabled, FPDAT[15:8] are used exclusively for the MediaPlug interface. Therefore, when the MediaPlug interface is enabled, Color 16-bit panels cannot be used without an external multiplexing circuit. For further information on the external circuit required, see the \textit{S1D13506 Hardware Functional Specification}, document number X25B-A-001-xx.

The MediaPlug interface requires a source clock between 8MHz and 19MHz to operate (optimal is 14.318MHz). By default, the MediaPlug software assumes a 14.318MHz frequency is available on CLKI2. If the frequency of CLKI2 is changed, software should reprogram the MediaPlug Clock Register (REG[01Ch]) to select a clock source that is suitable, or program the clock divide bits to obtain a frequency within the correct range.

If the S5U13506B00x evaluation board is used, the clock chip should be programmed to support a valid clock for the MediaPlug interface. The ICD2061A clock chip selects frequencies based on the states of GPIO1 and GPIO2. Since the MediaPlug interface uses the GPIO2 pin for camera power, it is important to program the clock chip for the correct MediaPlug interface frequency when the camera is both on or off (GPIO2 low or high). A HAL function is available which programs the clock chip for the MediaPlug interface.
13 Identifying the S1D13506

The S1D13506 can only be identified once the Memory/Register Select bit is set to 0. The steps to identify the S1D13506 are:

1. Set the Memory/Register Select bit to 0 by writing 00h to REG[001h].
2. Read REG[000h].
3. The production version of the S1D13506 will return a value of 11h (00010001b).
4. The product code is 4 (000100b based on bits 7-2).
5. The revision code is 1 (01b based on bits 1-0).
14 Hardware Abstraction Layer (HAL)

The HAL is a processor independent programming library designed to help port applications and utilities from one S1D13x0x product to another. Epson has provided this library as a result of developing test utilities for the S1D13x0x LCD controller products.

The HAL contains functions which are designed to be consistent between S1D13x0x products, but as the semiconductor products evolve, so must the HAL; consequently there are some differences between HAL functions for different S1D13x0x products.

Note
As the S1D13x0x line of products changes, the HAL may change significantly or cease to be a useful tool. Seiko Epson reserves the right to change the functionality of the HAL or discontinue its use if no longer required.

14.1 API for 13506HAL

This section is a description of the HAL library Application Programmers Interface (API). Updates and revisions to the HAL may include new functions not included in the following documentation.

Table 14-1: HAL Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Initialization</strong></td>
<td></td>
</tr>
<tr>
<td>seRegisterDevice</td>
<td>Registers the S1D13506 parameters with the HAL. seRegisterDevice MUST be the first HAL function called by an application.</td>
</tr>
<tr>
<td>seInitReg</td>
<td>Initializes the registers, LUT, and allocates memory for and assigns.</td>
</tr>
<tr>
<td>seGetHalVersion</td>
<td>Returns HAL library version information</td>
</tr>
<tr>
<td>seGetId</td>
<td>Identifies the controller by interpreting the revision code register.</td>
</tr>
<tr>
<td>seGetLibseVersion</td>
<td>Return version information on the LIBSE libraries (for non-x86 platforms)</td>
</tr>
<tr>
<td><strong>General HAL Support:</strong></td>
<td></td>
</tr>
<tr>
<td>seGetInstalledMemorySize</td>
<td>Returns the total size of the display buffer memory.</td>
</tr>
<tr>
<td>seGetAvailableMemorySize</td>
<td>Determines the last byte of display memory, before the Dual Panel buffer, available to an application.</td>
</tr>
<tr>
<td>seGetResolution</td>
<td>Retrieve the width and height of the physical display device.</td>
</tr>
<tr>
<td>seGetLcdResolution</td>
<td></td>
</tr>
<tr>
<td>seGetCrtResolution</td>
<td></td>
</tr>
<tr>
<td>seGetTvResolution</td>
<td></td>
</tr>
<tr>
<td>seGetBytesPerScanline</td>
<td>Returns the number of bytes in each scanline of the display including non-display size.</td>
</tr>
<tr>
<td>seGetLcdBytesPerScanline</td>
<td></td>
</tr>
<tr>
<td>seGetCrtBytesPerScanline</td>
<td></td>
</tr>
<tr>
<td>seGetTvBytesPerScanline</td>
<td></td>
</tr>
<tr>
<td>seSetSoftwareSuspend</td>
<td>Sets/resets software suspend mode.</td>
</tr>
<tr>
<td>seGetSoftwareSuspend</td>
<td>Returns the current software suspend state.</td>
</tr>
<tr>
<td>seCheckEndian</td>
<td>Retrieves the “ endian-ness” of the host CPU platform.</td>
</tr>
<tr>
<td>seGetLcdOrientation</td>
<td>Returns the SwivelView orientation of the LCD panel.</td>
</tr>
<tr>
<td>seDelay</td>
<td>Delays the given number of seconds before returning.</td>
</tr>
</tbody>
</table>
### Table 14-1: HAL Functions (Continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seDisplayBlank</td>
<td>Blank/unblank the display by disabling the FIFO.</td>
</tr>

14.2 Initialization

Initialization functions are normally the first functions in the HAL library that an application calls. These routine allow the application to learn a little about the controller and to prepare the HAL library for use.

**int seRegisterDevice(const LPHAL_STRUC lpHalInfo)**

**Description:** This function registers the S1D13506 device parameters with the HAL library. The device parameters include such item as address range, register values, desired frame rate, and more which are stored in the HAL_STRUCT structure pointed to by lpHalInfo. Additionally this routine allocates system memory as address space for accessing registers and the display buffer.

**Parameters:**

- **lpHalInfo** A pointer to a HAL_STRUCT structure. This structure must be filled with appropriate values prior to calling seRegisterDevice.

**Return Value:**

- **ERR_OK** operation completed with no problems
- **ERR_UNKNOWN_DEVICE** The HAL was unable to locate the S1D13506.
- **ERR_FAILED** The HAL was unable to map S1D13506 display memory to the host platform.

In addition, on Win32 platforms, the following two error values may be returned:

- **ERR_PCI_DRIVER_- NOT_FOUND** The HAL was unable to locate file S1D13X0X.VXD
- **ERR_PCI_BRIDGE_- ADAPTER_NOT_FOUND** The driver file S1D13X0X.VXD was unable to locate the S1D13506.

**Note**

seRegisterDevice() MUST be called before any other HAL functions.
int seInitReg(unsigned DisplayMode, unsigned Flags)

**Description:**
This function initializes the S1D13506 registers, the LUT, assigns default surfaces and allocates memory accordingly.

**Parameters:**
DisplayMode  
Set this parameter according to the type of initialization desired. Valid values for DisplayMode are:
- 0  Use the values configured by 13506CFG.EXE
- LCD  Initialize for use with an LCD panel.
- CRT  Initialize for use with a monitor.
- TV  Initialize for use with a TV
- LCD | CRT  Initialize for both LCD panel and monitor.
- LCD | TV  Initialize for both LCD panel and TV.

Flags  
Provides additional information about how to perform the initialization. Valid values for Flags are:
- CLEAR_MEMZero display memory as part of the initialization
- DISP_BLANKBlank the display, for aesthetics, during initialization.

**Return Value:**
- ERR_OK  The initialization completed with no problems.
- ERR_FAILED  seInitReg failed to initialize the system correctly.

void seGetHalVersion(const char ** pVersion, const char ** pStatus, const char **pStatusRevision)

**Description:**
Retrieves the HAL library version information. By retrieving and displaying the HAL version information along with application version information it is possible to determine at a glance whether the latest version of the software is being run.

**Parameters:**
- pVersion  A pointer to the array to receive the HAL version code.
- pStatus  A pointer to the array to receive the HAL status code
  
  A “B” designates a beta version of the HAL, a NULL indicates the release version
- pStatusRevision  A pointer to the array to receive the HAL revision status.

**Return Value:**
The version information is returned as the contents of the pointer arguments. A typical return might be:
- *pVersion == “1.01” (HAL version 1.01)
- *pStatus == “B” (BETA release)
- *pStatusRevision == “5” (fifth update of the beta)
**int seGetId(int * pId)**

**Description:**
Reads the S1D13506 revision code register to determine the controller product and revision.

**Parameters:**
- `pId` A pointer to an integer to receive the controller ID. The value returned is an interpreted version of the controller identification.

For the S1D13506 the return values are:
- `ID_S1D13506_REV0` S1D13506 Test Sample version.
- `ID_S1D13506_REV1` S1D13506 Production version
- `ID_UNKNOWN` The HAL was unable to identify the controller.

**Return Value:**
- `ERR_OK` The operation completed with no problems
- `ERR_UNKNOWN_DEVICE` Return value when `pId` is `ID_UNKNOWN`.

**Note**
- `seGetId()` will disable hardware suspend on x86 platforms, and enables the Memory/Register Select bit (REG[001h] bit 7) on all platforms.
14.2.1 General HAL Support

This category of HAL functions provide several essential services which do not readily group with other functions.

DWORD seGetInstalledMemorySize(void)

Description: This function returns the size of display buffer memory in bytes.

Memory size is determined during the call to seRegisterDevice() by reading the status of MD6 and MD7. seGetInstalledMemorySize() returns the memory size determined during the HAL initialization.

Parameters: None

Return Value: The return value is the size of the video memory buffer in bytes and will be either 80000h (512kb) or 200000h (2 MB).

DWORD seGetAvailableMemorySize(void)

Description: This function returns an offset to the last byte memory, before the Dual Panel buffer, accessible to an application.

An application can directly access memory from offset zero to the offset returned by this function. On most systems the return value will be the last byte of physical display memory. On systems configured for a dual STN panel the return value will account for the presence of the Dual Panel buffer.

Parameters: None.

Return Value: The return value is an offset to the last byte memory directly accessible to an application.
int seGetResolution(unsigned *Width, unsigned *Height)
void seGetLcdResolution(unsigned *Width, unsigned *Height)
void seGetCrtResolution(unsigned *Width, unsigned *Height)
void seGetTvResolution(unsigned *Width, unsigned *Height)

Description: These functions return the width and height of the physical display device. Virtual dimensions are not accounted for in the return value.

seGetResolution() returns the width and height of the active surface. If there is more than one display associated with the surface then precedence is given to the LCD.

seGetLcdResolution() returns the width and height of the LCD panel. The width and height are adjusted for SwivelView orientation.

seGetCrtResolution() and seGetTvResolution() return the width and height of the display indicated by the function name.

Parameters:

Width A pointer to an unsigned integer which will receive the width, in pixels, for the indicated surface.

Height A pointer to an unsigned integer which will receive the height, in pixels, for the indicated surface.

Return Value: seGetResolution() returns one of the following:

ERR_OK Function completed successfully
ERR_FAILED Returned when there is not an active display surface.

seGetLcdResolution(), seGetCrtResolution(), and seGetTvResolution() do not return any value.

unsigned seGetBytesPerScanline(void)
unsigned seGetLcdBytesPerScanline(void)
unsigned seGetTvBytesPerScanline(void)
unsigned seGetCrtBytesPerScanline(void)

Description: These functions return the number of bytes per scanline, including both displayed and non-displayed for the current video mode.

seGetBytesPerScanline() returns the number of bytes per scanline for the current active surface.

seGetLcdBytesPerScanline(), seGetTvBytesPerScanline(), and seGetCrtBytesPerScanline() return the number of bytes per scanline for the surface indicated in the function name.

To work correctly the S1D13505 registers have been initialized prior to calling any of these routines.

Parameters: None.

Return Value: The return value is the “stride” or number of bytes from the first byte of one scanline to the first byte of the next scanline. This value includes both the displayed and the non-displayed bytes on each logical scanline.

For rotated display modes the return value will be either 1024 (8 bpp) or 2048 (15/16 bpp) to reflect the 1024 x 1024 virtual area of the rotated memory.
void seSetSoftwareSuspend(BOOL Enable)

Description: This function enables or disables software power suspend.

When software suspend is enabled the S1D13506 reduces power consumption by making
the displays inactive and ignoring memory accesses. Disabling software suspend re-
ables the video system to full functionality.

Parameters: Enable Call with Enable set to TRUE to set software power suspend
Call with Enable set to FALSE to disable software power suspend.

Return Value: None.

BOOL seGetSoftwareSuspend(void)

Description: seGetSoftwareSuspend() returns the current state of software power suspend.

Parameters: None.

Return Value: The return value is TRUE if software suspend is enabled. The return FALSE if software
suspend is not enabled.

int seCheckEndian(BOOL *ReverseBytes)

Description: This function returns the “endian-ness” of the CPU the application is running on.

Parameters: ReverseBytes A pointer to boolean value to receive the endian-ness of the system. On
return from this function ReverseBytes is FALSE if the CPU is little
endian (i.e. Intel). ReverseBytes will be TRUE if the CPU is
big-endian (i.e. Motorola)

Return Value: The return value is always ERR_OK.

unsigned seGetLcdOrientation(void)

Description: This function retrieves the SwivelView orientation of the LCD display.

The SwivelView status is read directly from the S1D13506 registers. Calling this function
when the LCD display is not enabled will result in an erroneous return a value.

Note Only the LCD interface supports SwivelView. A CRT/TV is always assumed to be in
LANDSCAPE mode.

Parameters: None.

Return Value: LANDSCAPE Not rotated.
ROTATE90 Display is rotated 90 degrees clockwise.
ROTATE180 Display is rotated 180 degrees clockwise.
ROTATE270 Display is rotated 270 degrees.
int seDelay(DWORD Seconds)

Description: This function, intended for non-Intel platforms, delays for the specified number of seconds then returns to the calling routine. On several evaluation platforms it was not readily apparent where to obtain an accurate source of time delays. seDelay() was the result of the need to delay a specified amount of time on these platforms.

seDelay works by calculating and counting the number of vertical non-display periods in the requested delay time. This implies two conditions for proper operation:
a) The S1D13506 control registers must be configured to correct values.
b) Either the CRT or LCD display interface must be enabled.

On Intel and other supported platforms seDelay() calls the C library time functions to delay the desired amount of time.

Parameters:
Seconds The number of seconds to delay for.

Return Value:
ERR_OK Returned by all platforms at the completion of a successful delay.
ERR_FAILED Returned by platforms which do not have time functions in their standard C library and either of the operating conditions is violated.

void seDisplayBlank(BOOL Blank)
void seDisplayLcdBlank(BOOL Blank)
void seDisplayCrtBlank(BOOL Blank)
void seDisplayTvBlank(BOOL Blank)

Description: These functions blank the display by disabling the FIFO for the specified surface. Blank- ing the display is a fast convenient means of temporarily shutting down a display device. For instance updating the entire display in one write may produce a flashing or tearing effect. If the display is blanked prior to performing the update then the operation is perceived to be smoother and cleaner.

seDisplayBlank() will blank the display associated with the current active surface.
seDisplayLcdBlank(), seDisplayCrtBlank(), and seDisplayTvBlank() blank the display for the surface indicated in the function name.

Parameters:
Blank Call with Blank set to TRUE to blank the display. Call with Blank set to FALSE to un-blank the display.

Return Value: None.
void seDisplayEnable(BOOL Enable)
void seLcdDisplayEnable(BOOL Enable)
void seCrtDisplayEnable(BOOL Enable)
void seTvDisplayEnable(BOOL Enable)

Description:

These functions enable or disable the selected display device.

seDisplayEnable() enables or disables the display for the active surface.

seLcdDisplayEnable() enables or disables the LCD display.

seCrtDisplayEnable() enables or disables the CRT display. seCrtDisplayEnable() will disa-
ble CRT/TV PCLK 2X clock and as a side effect will disable TV, if the TV was enabled.

seTvDisplayEnable() enables or disables the TV display. If the CRT is enabled then seTv-
displayEnable() disables it. When seTvDisplayEnable is called the TV flicker filter is
enabled or disabled based on the values saved by the configuration program.

Parameters:

Enable       Call with Enable set to TRUE to enable the display device. Call with
              Enable set to FALSE to disable the device.

Return Value: None.
14.2.2 Advance HAL Functions

The advanced HAL functions include a level of access that most applications don’t will never need to access.

**int seBeginHighPriority(void)**

**Description:** Writing and debugging software under the Windows operating system greatly simplifies the developing process for the S1D13506 evaluation system. One issue which impedes application programming is that of latency. Time critical operations, performance measurement for instance, are not guaranteed any set amount of processor time.

This function raises the priority of the thread and virtually eliminates the question of latency for programs running on a Windows platform.

**Note**

The application should not leave it’s thread running in a high priority state for long periods of time. As soon as a time critical operation is complete the application should call seEndHighPriority().

**Parameters:** None.

**Return Value:** ERR_OK If the function completes successfully.

**int seEndHighPriority(void)**

**Description:** The function returns the thread priority of the calling application to normal.

After performing some time critical operation the application should call seEndHighPriority() to return the thread priority to a normal level.

**Parameters:** None.

**Return Value:** None.
int seSetClock(CLOCKSELECT ClockSelect, FREQINDEX FreqIndex)

Description: Call seSetClock() to set the clock rate of the programmable clock.

Parameters: ClockSelect The ICD2061A programmable clock chip supports two output clock
signals. ClockSelect chooses which of the two output clocks to adjust.

Valid ClockSelect values are defined by the HAL contents CLKI or
CLKI2

FreqIndex FreqIndex is an enumerated constant and determines what the output
frequency should be.

Valid values for FreqIndex are:
FREQ_6000 6.000 MHz
FREQ_10000 10.000 MHz
FREQ_14318 14.318 MHz
FREQ_17734 17.734 MHz
FREQ_20000 20.000 MHz
FREQ_24000 24.000 MHz
FREQ_25000 25.000 MHz
FREQ_25175 25.175 MHz
FREQ_28318 28.318 MHz
FREQ_30000 30.000 MHz
FREQ_31500 31.500 MHz
FREQ_32000 32.000 MHz
FREQ_33000 33.000 MHz
FREQ_33333 33.333 MHz
FREQ_34000 34.000 MHz
FREQ_35000 35.000 MHz
FREQ_36000 36.000 MHz
FREQ_40000 40.000 MHz
FREQ_49500 49.500 MHz
FREQ_50000 50.000 MHz
FREQ_56250 56.250 MHz
FREQ_65000 65.000 MHz
FREQ_80000 80.000 MHz

Return Value: ERR_OK The function completed with no problems.
ERR_FAILED seSetClock failed the cause may be an invalid ClockSelect or an
invalid frequency index

Note
If seSetClock is called with a ClockSelect of CLKI2 and FreqIndex of FREQ_17734
then the HAL will bypass the programmable clock and select the Feature Clock as the
input clock source. This is done with the assumption that the application is setting up for
TV output and the Feature Clock oscillator will provide a more stable clock for use with
TV. (The feature oscillator must be 17.734 MHz)
14.2.3 Surface Support

The S1D13506 HAL library depends heavily on the concept of surfaces. Through surfaces the HAL tracks memory requirements of the attached display devices, hardware cursor and ink layers, and the Dual Panel buffer.

Surfaces allow the HAL to permit or fail function calls which change the geometry of the S1D13506 display memory. Most HAL functions either allocate surface memory or manipulate a surface that has been allocated.

The functions in this sections allow the application programmer a little greater control over surfaces.

**int seGetSurfaceDisplayMode(void)**

**Description:**
This function determines the type of display associated with the current active surface.

**Parameters:**
None.

**Return Value:**
The return value indicates the active surface display type. Return values will be one of:

- **LCD** The LCD panel is the active surface.
- **CRT** The CRT display is the active surface.
- **TV** The TV is the active display.

**DWORD seGetSurfaceSize(void)**

**Description:**
This function returns the number of display memory bytes allocated to the current active surface. The return value does not account for the size for the hardware cursor or ink layer which may be associated with the surface.

**Parameters:**
None.

**Return Value:**
The return value is the number of bytes allocated to the current active surface. The return value can be 0 if this function is called before initializing and making active a surface.

**DWORD seGetSurfaceLinearAddress(void)**

**Description:**
This function returns the linear address of the start of memory for the active surface.

**Parameters:**
None.

**Return Value:**
The return value is the linear address to the start of memory for the active surface. A linear address is a 32-bit offset, in CPU address space.

The return value will be NULL if this function is called before a surface has been initialized and made active.

**Note**
On 16-bit Intel platforms, this function will always return NULL. The PCI memory may be located beyond the addressing range of 16-bit programs so all S1D13505 controller accesses must be made through the HAL.
DWORD seGetSurfaceOffsetAddress(void)

Description: This function returns the offset, from the first byte of display memory to the first byte of memory associated with the active display surface.

Parameters: None.

Return Value: The return value is the offset, in bytes, from the start of display memory to the start of the active surface. An address of 0 indicates the surface starts in the first byte of display buffer memory.

Note
This function also returns 0 if there is no memory allocated to an active surface. You must ensure that memory is allocated before calling seGetSurfaceOffsetAddress().

DWORD seAllocLcdSurface(DWORD Size)
DWORD seAllocCrtSurface(DWORD Size)
DWORD seAllocTvSurface(DWORD Size)

Description: These functions allocate display buffer memory for a surface. If the surface previously had memory allocated then that memory is first released. Newly allocated memory is not cleared.

Call seAllocLcdSurface(), seAllocCrtSurface(), and seAllocTvSurface() to allocate the requested amount of display memory for the indicated surface.

These functions allow an application to bypass the automatic surface allocation which occurs when functions such as seInitReg() or seSetBitsPerPixel() are called.

Parameters: Size The size in bytes of the requested memory block.

Return Value: If the memory allocation succeeds then the return value is the linear address of the allocated memory. If the allocation fails then the return value is 0. A linear address is a 32-bit offset, in CPU address space.

int seFreeSurface(DWORD LinearAddress)

Description: This function can be called to free any previously allocated display buffer memory.

This function is intended to complement seAllocLcdSurface(), seAllocCrtSurface(), and seAllocTvSurface(). seFreeSurface can be used to free memory allocated for the hardware cursor and ink layer however it is recommended that seFreeCursor() or seFreeInk() be called for these surfaces.

After calling one of these functions the application must switch the active surface to one which has memory allocated before calling any drawing functions.

Parameters: LinearAddress A valid linear address. The linear address is a dword returned to the application by any surface allocation call.

Return Value: ERR_OK Function completed successfully.
ERR_FAILED Function failed.
void seSetLcdAsActiveSurface(void)
void seSetCrtAsActiveSurface(void)
void seSetTvAsActiveSurface(void)

Description: These functions set the active surface to the display indicated in the function name.
Before calling one of these surface selection routines, that surface must have been allocated using any of the surface allocation methods.

Parameters: None.

Return Value: None.
14.2.4 Register Access

The Register Access functions provide convenient method of accessing the control registers of the S1D13506 controller using byte, word or dword widths.

To reduce the overhead of the function call as much as possible, two steps were taken:

- To gain maximum efficiency on all compilers and platforms, byte and word size arguments are passed between the application and the HAL as unsigned integers. This typically allows a compiler to produce more efficient code for the platform.

- Index alignment for word and dword accesses is not tested. On non-Intel platforms attempting to access a word or dword on a non-aligned boundary may result in a processor trap. It is the responsibility of the caller to ensure that the requested index offset is correctly aligned for the target platform.

unsigned seReadRegByte(DWORD Index)
Description: This routine reads the register specified by Index and returns the value.
Parameters: Index Offset, in bytes, to the register to read.
Return Value: The return value is the byte read from the register.

unsigned seReadRegWord(DWORD Index)
Description: This routine read two consecutive registers as a word and returns the value.
Parameters: Index Offset to the first register to read.
Return Value: The return value is the word read from the S1D13506 registers.

DWORD seReadRegDword(DWORD Index)
Description: This routine reads four consecutive registers as a dword and returns the value.
Parameters: Index Offset to the first of the four registers to read.
Return Value: The return value is the dword read from the S1D13506 registers.

int seWriteRegByte(DWORD Index, unsigned Value)
Description: This routine writes Value to the register specified by Index.
Parameters: Index Offset to the register to be written
Value The value, in the least significant byte, to write to the register
Return Value: None
void seWriteRegWord(DWORD Index, unsigned Value)

Description: This routine writes the word contained in Value to the specified index.

Parameters:
- Index Offset to the register pair to be written.
- Value The value, in the least significant word, to write to the registers.

Return Value: None.

void seWriteRegDword(DWORD Index, DWORD Value)

Description: This routine writes the value specified to four registers starting at Index.

Parameters:
- Index Offset to the register to be written to.
- Value The dword value to be written to the registers.

Return Value: None.
14.2.5 Memory Access

The Memory Access functions provide convenient method of accessing the display memory on an S1D13506 controller using byte, word or dword widths.

To reduce the overhead of these function calls as much as possible, two steps were taken:

- To gain maximum efficiency on all compilers and platforms, byte and word size arguments are passed between the application and the HAL as unsigned integers. This typically allows a compiler to produce more efficient code for the platform.

- Offset alignment for word and dword accesses is not tested. On non-Intel platforms attempting to access a word or dword on a non-aligned boundary may result in a processor trap. It is the responsibility of the caller to ensure that the requested offset is correctly aligned for the target platform.

unsigned seReadDisplayByte(DWORD Offset)
Description: Reads a byte from the display buffer memory at the specified offset and returns the value.
Parameters: Offset Offset, in bytes, from start of the display buffer to the byte to read.
Return Value: The return value, in the least significant byte, is the byte read from display memory.

unsigned seReadDisplayWord(DWORD Offset)
Description: Reads one word from display buffer memory at the specified offset and returns the value.
Parameters: Offset Offset, in bytes, from start of the display buffer to the word to read.
Return Value: The return value, in the least significant word, is the word read from display memory.

DWORD seReadDisplayDword(DWORD Offset)
Description: Reads one dword from display buffer memory at the specified offset and returns the value.
Parameters: Offset Offset, in bytes, from start of display buffer to the dword to read.
Return Value: The DWORD read from display memory.

void seWriteDisplayBytes(DWORD Offset, unsigned Value, DWORD Count)
Description: This routine writes one or more bytes to the display buffer at the offset specified by Offset.
Parameters: Offset Offset, in bytes, from start of display memory to the first byte to be written.
Value An unsigned integer containing the byte to be written in the least significant byte.
Count Number of bytes to write. All bytes will have the same value.
Return Value: None.
Note
If ((Offset + Count) > memory size) then this function limits the writes to the end of display memory.

void seWriteDisplayWords(DWORD Offset, unsigned Value, DWORD Count)
Description: This routine writes one or more words to display memory starting at the specified offset.
Parameters:
Offset Offset, in bytes, from the start of display memory to the first word to write.
Value An unsigned integer containing the word to written in the least significant word.
Count Number of words to write. All words will have the same value.
Return Value: None.

Note
If ((Offset + (Count * 2)) > memory size) then this function limits the writes to the end of display memory.

void seWriteDisplayDwords(DWORD Offset, DWORD Value, DWORD Count)
Description: This routine writes one or more dwords to display memory starting at the specified offset.
Parameters:
Offset Offset, in bytes, from the start of display memory to the first dword to write.
Value The value to be written to display memory.
Count Number of dwords to write. All dwords will have the same value.
Return Value: None.

Note
If ((Offset + (Count * 4)) > memory size) then this function limits the writes to the end of display memory.
14.2.6 Color Manipulation

The functions in the Color Manipulation section deal with altering the color values in the Look-Up Table directly through the accessor functions and indirectly through the color depth setting functions.

Keep in mind that all lookup table data is contained in the upper nibble of each byte.

void seWriteLutEntry(int Index, BYTE *pRGB)
void seWriteLcdLutEntry(int Index, BYTE *pRGB)
void seWriteCrtLutEntry(int Index, BYTE *pRGB)
void seWriteTvLutEntry(int Index, BYTE *pRGB)

Description:
These routines write one lookup table entry to the specified index of the lookup table.

seWriteLutEntry() writes to the specified index of the current active surface. See seSetLcdAsActiveSurface(), seSetCrtAsActiveSurface() and seSetTvAsActiveSurface() for information about changing the active surface.

seWriteLcdLutEntry(), seWriteCrtLutEntry() and seWriteTvLutEntry() modify one entry of the lookup table of the surface indicated by the function name.

Parameter:
Index Offset to the lookup table entry to be modified. (i.e. a 0 will write the first entry and a 255 will write the last lookup table entry)
pRGB A pointer to byte array of data to write to the lookup table. The array must consist of three bytes; the first byte contains the red value the second byte contains the green value and the third byte contains the blue value.

Return Value: None
void seReadLutEntry(int Index, BYTE *pRGB)
void seReadLcdLutEntry(int Index, BYTE *pRGB)
void seReadCrtLutEntry(int Index, BYTE *pRGB)
void seReadTvLutEntry(int Index, BYTE *pRGB)

Description: These routines read one lookup table entry and return the results in the byte array pointed to by pRGB.

seReadLutEntry() reads the specified index from the lookup table of the current active surface. See seSetLcdAsActiveSurface(), seSetCrtAsActiveSurface() and seSetTvAsActiveSurface() for information about changing the active surface.

seReadLcdLutEntry(), seReadCrtLutEntry(), and seReadTvLutEntry() read one entry form the lookup table for the surface indicated by the function name.

Parameter:    Index    Offset to the lookup table entry to be read. (i.e. setting index to 2 will return a the value of the third element of the lookup table)
               pRGB    A pointer to an array to receive the lookup table data. The array must be at least three bytes long. On return from this function the first byte of the array will contain the red data, the second byte will contain the green data and the third byte will contain the blue data.

Return Value: None.

void seWriteLut(BYTE *pRGB, int Count)
void seWriteLcdLut(BYTE *pRGB, int Count)
void seWriteCrtLut(BYTE *pRGB, int Count)
void seWriteTvLut(BYTE *pRGB, int Count)

Description: These routines write one or more lookup table entries starting at offset zero.

seWriteLut() modifies Count entries in the current active surface. See seSetLcdAsActiveSurface(), seSetCrtAsActiveSurface() and seSetTvAsActiveSurface() for information about changing the active surface.

seWriteLcdLut(), seWriteCrtLut(), and seWriteTvLut() modifies the lookup table for the surface indicated in the function name.

This routine is intended to allow setting as many lookup table entries as the current color depth allows in call.

Parameter:    pRGB    A pointer to an array of lookup table entry values to write to the LUT. Each lookup table entry must consist of three bytes. The first byte must contain the red value, the second byte must contain the green value and the third byte must contain the blue value to modify the lookup table with.
               Count    The number of lookup table entries to modify.

Return Value: None.
void seReadLut(BYTE *pRGB, int Count)
void seReadLcdLut(BYTE *pRGB, int Count)
void seReadCrtLut(BYTE *pRGB, int Count)
void seReadTvLut(BYTE *pRGB, int Count)

Description:
This routine reads one or more lookup table entries and returns the result in the array pointed to by pRGB. The read always begins at the first lookup table entry.

seReadLut() reads the first Count lookup table entries from the current active surface. See seSetLcdAsActiveSurface(), seSetCrtAsActiveSurface() and seSetTvAsActiveSurface() for information about changing the active surface.

seReadLcdLut(), seReadCrtLut(), and seReadTvLut() read the first Count entries from the surface indicated by the function name.

This routine allows reading all the lookup table elements used by the current color depth in one library call.

Parameters:
pRGB A pointer to an array of bytes large enough to hold the requested number of lookup table entries. Each lookup table entry consists of three bytes; the first byte will contain the red data, the second the green data and the third the blue data.

Count The number of lookup table entries to read.

Return Value:
None.

DWORD seSetBitsPerPixel(unsigned BitsPerPixel)
DWORD seSetLcdBitsPerPixel(unsigned BitsPerPixel)
DWORD seSetCrtBitsPerPixel(unsigned BitsPerPixel)
DWORD seSetTvBitsPerPixel(unsigned BitsPerPixel)
DWORD seSetLcdCrtBitsPerPixel(unsigned BitsPerPixel)
DWORD seSetLcdTvBitsPerPixel(unsigned BitsPerPixel)

Description:
These functions change the color depth of the display and update the appropriate LUT. Display memory is automatically released and then reallocated as necessary for the display size.

seSetBitsPerPixel() changes the bits-per-pixel mode for the active surface. Memory is reassigned according to the descriptions for each of the following mode sets.

seSetLcdBitsPerPixel() changes the bits-per-pixel mode for the panel display. This function uses the current register settings for SwivelView to determine the amount of memory to allocate, and what starting register addresses are required.

Note
seSetLcdBitsPerPixel() frees CRT/TV memory in order to guarantee the LCD image starts at the beginning of display buffer memory.

seSetCrtBitsPerPixel() and seSetTvBitsPerPixel() change the bits-per-pixel mode for the indicated display device. These functions ignore the rotate90 and rotate180 register bits. Memory is allocated only for the landscape mode.
seSetLcdCrtBitsPerPixel() and seSetLcdTvBitsPerPixel() change the color depth for a surface which combines LCD and CRT/TV. Portrait (SwivelView 90) is disabled. If the display resolution is not the same for the two displays then memory is allocated based on the larger of the two.

**IMPORTANT**

When the LCD color depth is changed, memory allocated for the display buffer and ink layer/hardware cursors is freed and the display buffer memory is reassigned. The application must redraw the display and re-initialize the cursor/ink and redraw after calling seSetBitsPerPixel().

seSetLcdCrtBitsPerPixel(), and seSetLcdTvBitsPerPixel() will free all allocated memory for all displays and all ink layers/hardware cursors, then allocate memory only for the display(s) mentioned in the function name. The cursor/ink must be re-initialized and restored after making one of these calls.

If the active surface is the panel then seSetBitsPerPixel() will free all allocated memory for all displays and all ink layers/hardware cursors, then allocate memory ONLY for the active surface (LCD). If the active surface is the CRT or TV, seSetBitsPerPixel() will free memory only for the active surface (CRT or TV), and then reallocate memory for this surface as required.

**Parameters:**

- **BitsPerPixel**
  The new color depth. BitsPerPixel can be one of the following:
  - 4, 8, 15, 16.

**Return Value:**

- The return value is the thirty-two bit offset to the start of the surface display memory. If there is an error the return value is 0. A linear address is the 32-bit offset, in CPU address space, where the application can directly read or write display memory.

  The thirty-two bit address must be converted to a segment:offset for use with a 16-bit Intel platform.

**unsigned seGetBitsPerPixel(void)**

**unsigned seGetLcdBitsPerPixel(void)**

**unsigned seGetCrtBitsPerPixel(void)**

**unsigned seGetTvBitsPerPixel(void);**

**Description:**

These functions returns the current color depth for a the associated display surface.

seGetBitsPerPixel() returns the color depth for the current active surface.

seGetLcdBitsPerPixel(), seGetCrtBitsPerPixel(), and seGetTvBitsPerPixel() return the color depth for the surface indicated in the function name.

**Parameters:**

- None.

**Return Value:**

- The color depth of the surface. This value will be 4, 8, 15 or 16.
14.2.7 Virtual Display

int seVirtInit(DWORD Width, DWORD Height)
int seLcdVirtInit(DWORD Width, DWORD Height)
int seCrtVirtInit(DWORD Width, DWORD Height)
int seTvVirtInit(DWORD Width, DWORD Height)
int seLcdCrtVirtInit(DWORD Width, DWORD Height)
int seLcdTvVirtInit(DWORD Width, DWORD Height)

Description:
These functions prepare the S1D13506 for displaying a virtual image.

“Virtual Image” describes the condition where the image contained in display memory is larger than the physical display. In this situation the display surface is used as a window into the larger display memory area. Panning (right/left) and scrolling (up/down) are used move the display surface in order to view the entire image a portion at a time.

seVirtInit() prepares the current active surface for virtual image display. Memory is allocated based on width, height and the current color depth.

seLcdVirtInit initializes and allocates memory for the LCD based on width and height and color depth. If the panel surface is rotated 90 or 270 degrees then the height is limited to a maximum 1024 lines.

seCrtVirtInit and seTvVirtInit initialize and allocate memory for the given display based on current width and height and color depth.

seLcdCrtVirtInit and seLcdTvVirtInit initialize and allocate memory for a surface which combines both LCD and CRT/TV. Memory is allocated based on the requirements of the larger of the two surfaces (if different). If the panel surface is rotated 90 or 270 degrees then the height is limited to a maximum of 1024 lines.

Memory previously allocated for this surface is released then reallocated to the larger size.

Parameters:

Width
The desired virtual width of the display in pixels.
Width must be a multiple of the number of pixels contained in one word of display memory. At 15/16 bit per pixel Width may be any value. At 8 bit per pixel Width must be a multiple of two and at 4 bit per pixel Width must be a multiple of four.

Height
The desired virtual height of the display in pixels.

The HAL performs internal memory management to ensure that all display surfaces and cursor/ink layer have sufficient memory for operation. The Height parameter is required so the HAL can determine the amount of memory the application requires for the virtual image.

Return Value:

ERR_OK
The function completed successfully.

ERR_HAL_BAD_ARG
The requested virtual dimensions are smaller than the physical display size.

ERR_NOT_ENOUGH_MEMORY
There is insufficient free display memory to set the requested virtual display size.
void seVirtPanScroll(DWORD x, DWORD y)
void seLcdVirtPanScroll(DWORD x, DWORD y)
void seCrtVirtPanScroll(DWORD x, DWORD y)
void seTvVirtPanScroll(DWORD x, DWORD y)
void seLcdCrtVirtPanScroll(DWORD x, DWORD y)
void seLcdTvVirtPanScroll(DWORD x, DWORD y)

Description: When displaying a virtual image the display surface is smaller than the virtual image contained in display memory. In order to view the entire image the display is treated as a window into the virtual image.

These functions allow an application to pan (right and left) and scroll (up and down) the display over the virtual image.

seVirtPanScroll() will pan and scroll the current active surface.
seLcdVirtPanScroll(), seCrtVirtPanScroll(), seTvVirtPanScroll(), seLcdCrtVirtPanScroll(), and seLcdTvVirtPanScroll() will pan and scroll the surface indicated in the function name.

Parameters:

- x The new x offset, in pixels, of the upper left corner of the display.
- y The new y offset, in pixels, of the upper left corner of the display.

Return Value: None.
14.2.8 Drawing

Functions in this category perform primitive drawing on the specified display surface. Supported drawing primitive include pixels, lines, rectangles, ellipses and circles.

void seSetPixel(long x, long y, DWORD Color)
void seSetLcdPixel(long x, long y, DWORD Color)
void seSetCrtPixel(long x, long y, DWORD Color)
void seSetTvPixel(long x, long y, DWORD Color)

Description: These routines set a pixel at the location x,y with the specified color.

Use seSetPixel() to set one pixel on the current active surface. See seSetLcdAsActiveSurface(), seSetCrtAsActiveSurface() and seSetTvAsActiveSurface() for information about changing the active surface.

Use seSetLcdPixel(), seSetCrtPixel(), and seSetTvPixel() to set one pixel on the surface indicated in the function name.

Parameters:

x The X co-ordinate, in pixels, of the pixel to set.
y The Y co-ordinate, in pixels, of the pixel to set.
Color Specifies the color to draw the pixel with. Color is interpreted differently at different color depths.

At 4 and 8 bit per pixel display colors are derived from the lookup table values. The least significant byte of Color forms an index into the lookup table.

At 15 and 16 bit per pixel the lookup table is bypassed and each word of display memory forms the color to display. At 15 bit per pixel the least significant word directly represents the color to draw the pixel with as a 5-5-5 RGB value with the most significant bit of the word discarded. In 16 bit per pixel display mode the least significant word describes the color to draw the pixel with in 5-6-5 RGB format.

Return Value: None.
DWORD seGetPixel(long x, long y)
DWORD seGetLcdPixel(long x, long y)
DWORD seGetCrtPixel(long x, long y)
DWORD seGetTvPixel(long x, long y)

Description: Returns the pixel color at the specified display location

Use seGetPixel() to read the pixel color at the specified x,y co-ordinates on the current active surface. See seSetLcdAsActiveSurface(), seSetCrtAsActiveSurface() and seSetTvAsActiveSurface() for information about changing the active surface.

Use seGetLcdPixel(), seGetCrtPixel(), and seGetTvPixel() to read the pixel color at the specified x,y co-ordinate on the display surface referenced in the function name.

Parameters:  
x The X co-ordinate, in pixels, of the pixel to read  
y The Y co-ordinate, in pixels, of the pixel to read

Return Value: The return value is a dword describing the color read at the x,y co-ordinate. Color is interpreted differently at different color depths.

At 4 and 8 bit per pixel, display colors are derived from the lookup table values. The return value is an index into the lookup table. The red, green and blue components of the color can be determined by reading the lookup table values at the returned index.

At 15 and 16 bit per pixel the lookup table is bypassed and each word of display memory form the color to display. At 15 bit per pixel the least significant word of the return value directly represents the color of the pixel as a 5-5-5 RGB value with the most significant bit of the word discarded. In 16 bit per pixel display mode the least significant word of the return value describes the color as a 5-6-5 RGB value.
void seDrawLine(long x1, long y1, long x2, long y2, DWORD Color)
void seDrawLcdLine(long x1, long y1, long x2, long y2, DWORD Color)
void seDrawCrtLine(long x1, long y1, long x2, long y2, DWORD Color)
void seDrawTvLine(long x1, long y1, long x2, long y2, DWORD Color)

**Description:**
These functions draw a line between two points in the specified color.

Use `seDrawLine()` to draw a line on the current active surface. See `seSetLcdAsActiveSurface()`, `seSetCrtAsActiveSurface()` and `seSetTvAsActiveSurface()` for information about changing the active surface.

Use `seDrawLcdLine()`, `seDrawCrtLine()`, and `seDrawTvLine()` to draw a line on the surface referenced by the function name.

**Parameters:**
- **x1**
  The X co-ordinate, in pixels, of the first endpoint of the line to be drawn.
- **y1**
  The Y co-ordinate, in pixels, or the first endpoint of the line to be drawn.
- **x2**
  The X co-ordinate, in pixels, of the second endpoint of the line to be drawn.
- **y2**
  The Y co-ordinate, in pixels, of the second endpoint of the line to be drawn.
- **Color**
  Specifies the color to draw the line with. Color is interpreted differently at different color depths.
  
  At 4 and 8 bit per pixel display colors are derived from the lookup table values. The least significant byte of Color is an index into the lookup table.
  
  At 15 and 16 bit per pixel the lookup table is bypassed and each word of display memory forms the color to display. At 15 bit per pixel the least significant word directly represents the color to draw the line with as a 5-5-5 RGB value with the most significant bit of the word discarded. In 16 bit per pixel display mode the least significant word describes the color to draw the line with in 5-6-5 RGB format.

**Return Value:**
None.
void seDrawRect(long x1, long y1, long x2, long y2, DWORD Color, BOOL SolidFill)
void seDrawLcdRect(long x1, long y1, long x2, long y2, DWORD Color, BOOL SolidFill)
void seDrawCrtRect(long x1, long y1, long x2, long y2, DWORD Color, BOOL SolidFill)
void seDrawTvRect(long x1, long y1, long x2, long y2, DWORD Color, BOOL SolidFill)

Description:
These routines draw a rectangle on the screen in the specified color. The rectangle is bounded on the upper left by the co-ordinate x1,y1 and on the lower right by the co-ordinate x2,y2. The SolidFill parameter allows the programmer to select whether to fill the interior or the rectangle or to only draw the border.

Use seDrawRect() to draw a rectangle on the current active display surface. See seSetLcdAsActiveSurface(), seSetCrtAsActiveSurface() and seSetTvAsActiveSurface() for information about changing the active surface.

Use seDrawLcdRect(), seDrawCrtRect(), and seDrawTvRect() to draw a rectangle on the display surface indicated by the function name.

Parameters:
x1 The X co-ordinate, in pixels, of the upper left corner of the rectangle.
y1 The Y co-ordinate, in pixels, of the upper left corner of the rectangle.
x2 The X co-ordinate, in pixels, of the lower right corner of the rectangle.
y2 The Y co-ordinate, in pixels, of the lower right corner of the rectangle.
Color Specifies the color to draw the line with. Color is interpreted differently at different color depths.
At 4 and 8 bit per pixel display colors are derived from the lookup table values. The least significant byte of Color is an index into the lookup table.
At 15 and 16 bit per pixel the lookup table is bypassed and each word of display memory forms the color to display. At 15 bit per pixel the least significant word directly represents the color to draw the line with as a 5-5-5 RGB value with the most significant bit of the word discarded. In 16 bit per pixel display mode the least significant word describes the color to draw the line with in 5-6-5 RGB format.
SolidFill A boolean value specifying whether to fill the interior of the rectangle.
Set to FALSE “0” to draw only the rectangle border. Set to TRUE “non-zero” to instruct this routine to fill the interior of the rectangle.

Return Value: None
void seDrawCircle(long xCenter, long yCenter, long Radius, DWORD Color)
void seDrawLcdCircle(long xCenter, long yCenter, long Radius, DWORD Color)
void seDrawCrtCircle(long xCenter, long yCenter, long Radius, DWORD Color)
void seDrawTvCircle(long xCenter, long yCenter, long Radius, DWORD Color)

Description: These routines draw a circle on the screen in the specified color. The circle is centered at the co-ordinate x, y and is drawn with the specified radius and Color. Circles cannot be solid filled.

Use seDrawCircle() to draw the circle on the current active display surface. See seSetLcdAsActiveSurface(), seSetCrtAsActiveSurface() and seSetTvAsActiveSurface() for information about changing the active surface.

Use seDrawLcdCircle(), seDrawCrtCircle(), seDrawTvCircle() draw the circle on the display surface indicated by the function name.

Parameters:

x The X co-ordinate, in pixels, of the center of the circle.
y The Y co-ordinate, in pixels, or the center of the circle.
Radius Specifies the radius of the circle in pixels.
Color Specifying the color to draw the circle. Color is interpreted differently at different color depths.

At 4 and 8 bit per pixel display colors are derived from the lookup table values. The least significant byte of Color is an index into the lookup table.

At 15 and 16 bit per pixel the lookup table is bypassed and each word of display memory forms the color to display. At 15 bit per pixel the least significant word directly represents the color to draw the circle with as a 5-5-5 RGB value with the most significant bit of the word discarded. In 16 bit per pixel display mode the least significant word describes the color to draw the circle with in 5-6-5 RGB format.

Return Value: None.
void seDrawEllipse(long xc, long yc, long xr, long yr, DWORD Color)
void seDrawLcdEllipse(long xc, long yc, long xr, long yr, DWORD Color)
void seDrawCrtEllipse(long xc, long yc, long xr, long yr, DWORD Color)
void seDrawTvEllipse(long xc, long yc, long xr, long yr, DWORD Color)

Description: These routines draw an ellipse on the screen in the specified color. The circle is centered at the co-ordinate x,y and is drawn in the specified color with the indicated radius for the x and y axis. Ellipses cannot be solid filled.

Use seDrawEllipse() to draw the circle on the current active display surface. See seSetLcdAsActiveSurface(), seSetCrtAsActiveSurface() and seSetTvAsActiveSurface() for information about changing the active surface.

Use seDrawLcdEllipse(), seDrawCrtEllipse(), seDrawTvEllipse() draw the ellipse on the display surface indicated by the function name

Parameters:
xc The X co-ordinate, in pixels, of the center of the ellipse.
yc The Y co-ordinate, in pixels, of the center of the ellipse.
xr A long integer specifying the X radius of the ellipse, in pixels.
yr A long integer specifying the Y radius of the ellipse, in pixels.
Color A dword specifying the color to draw the ellipse. Color is interpreted differently at different color depths.

At 4 and 8 bit per pixel display colors are derived from the lookup table values. The least significant byte of Color is an index into the lookup table.

At 15 and 16 bit per pixel the lookup table is bypassed and each word of display memory forms the color to display. At 15 bit per pixel the least significant word directly represents the color to draw the ellipse with as a 5-5-5 RGB value with the most significant bit of the word discarded. In 16 bit per pixel display mode the least significant word describes the color to draw the circle with in 5-6-5 RGB format.

Return Value: None.
14.2.9 Hardware Cursor

The routines in this section support hardware cursor. Most of the calls look similar to normal drawing calls (i.e. seDrawCursorLine()); however, these calls remove the programmer from having to know the particulars of the cursor memory location, layout and whether portrait mode is enabled.

The same S1D13506 uses the same hardware for both hardware cursor and ink layer which means that only the cursor or the ink layer can be active at any given time. The difference between the hardware cursor and the ink layer is that in cursor mode the image is a maximum of 64x64 pixels and can be moved around the display while in ink layer mode the image is as large as the physical size of the display and is fixed in position. Both the ink layer and hardware cursor have the same number of colors and handle these colors identically.

DWORD seInitCursor(void)
DWORD seInitLcdCursor(void)
DWORD seInitCrtCursor(void)
DWORD seInitTvCursor(void)

Description: These functions allocate cursor memory, fills the cursor image with a transparent block, and enable the cursor. If memory was previously allocated for the cursor, this memory is first released.

The S1D13506 supports two independent hardware cursors, one on a panel surface and one on the CRT/TV surface.

Use seInitCursor() to initialize the cursor for the active surface.

Use seInitLcdCursor(), seInitCrtCursor(), and seInitTvCursor() initialize the cursor on the display surface indicated in the function name.

Parameters: None.

Return Value: The return value is the thirty-two bit offset to the start of the hardware cursor memory. If there is an error the return value is 0.

Note
On a 16-bit DOS the return value must be converted into a segment:offset before use.
void seFreeCursor(void)
void seFreeLcdCursor(void)
void seFreeCrtCursor(void)
void seFreeTvCursor(void)

Description: These functions release memory allocated to the hardware cursor by seInitCursor() functions.

Use seFreeCursor() to free the hardware cursor memory for the current active surface.
Use seFreeLcdCursor(), seFreeCrtCursor(), and seFreeTvCursor() to free the resources associated with the surface indicated by the function name.

Parameters: None.
Return Value: None.

void seEnableCursor(int Enable)
void seEnableLcdCursor(int Enable)
void seEnableCrtCursor(int Enable)
void seEnableTvCursor(int Enable)

Description: These functions enable or disable the hardware cursor. When enabled the cursor will be visible on the display surface. When disabled the cursor will not be displayed.

Call seEnableCursor() to enable/disable the hardware cursor of the active surface.
Call seEnableLcdCursor(), seEnableCrtCursor(), and seEnableTvCursor() to enable/disable the hardware cursor for the surface indicated by the function name.
Recall that the CRT and TV share the same cursor. Enabling/disabling the cursor for one device will affect the other display as well.

Parameters: Enable A flag indicating whether to enable or disable the hardware cursor.
Call with Enable set to FALSE “0” to disable the hardware cursor for the surface. Call with Enable set to TRUE “non-0” to enable the hardware cursor for the device.

Return Value: None.
DWORD seGetCursorLinearAddress(void)
DWORD seGetLcdCursorLinearAddress(void)
DWORD seGetCrtCursorLinearAddress(void)
DWORD seGetTvCursorLinearAddress(void)

**Description:** These routines return address for the hardware cursor through which the application can directly access the cursor memory.

Call seGetCursorLinearAddress() to retrieve the address of the hardware cursor associated with the current active surface.

Call seGetLcdCursorLinearAddress(), seGetCrtCursorLinearAddress(), or seGetTvCursorLinearAddress() to retrieve the address of the hardware cursor associated with the display surface indicated by the function name.

**Parameters:** None.

**Return Value:** The return value is the linear address of the hardware cursor. A linear address is the 32 bit offset in CPU address space where the application can directly read or write the hardware cursor.

DWORD seGetCursorOffsetAddress(void)
DWORD seGetLcdCursorOffsetAddress(void)
DWORD seGetCrtCursorOffsetAddress(void)
DWORD seGetTvCursorOffsetAddress(void)

**Description:** These routines return the offset in display memory of the hardware cursor. Using this offset the application can use HAL API calls such as seSetWriteDisplayBytes() to access the hardware cursor image.

Call seGetCursorOffsetAddress() to get the offset to the hardware cursor associated with the current active surface.

Call seGetLcdCursorOffsetAddress(), seGetCrtCursorOffsetAddress(), and seGetTvCursorOffsetAddress() to retrieve the offset to the hardware cursor for the surface indicated in the function name.

**Parameters:** None.

**Return Value:** The return value is the offset, in bytes, from the start of display memory to the start of the hardware cursor.
void seMoveCursor(long x, long y)
void seMoveLcdCursor(long x, long y)
void seMoveCrtCursor(long x, long y)
void seMoveTvCursor(long x, long y)

Description:  These routines are move where the hardware cursor is shown on the display surface.
               Call seMoveCursor() to move the hardware cursor on the current active surface.
               Call seMoveLcdCursor(), seMoveCrtCursor(), and seMoveTvCursor() to move the hardware cursor associated with the surface indicated in the function name.

Parameter:  

x  The desired display surface X co-ordinate, in pixels, of the upper left corner of the cursor.

y  The desired display surface Y co-ordinate, in pixels, of the upper left corner of the cursor.

Return Value:  None.

void seSetCursorColor(int Index, DWORD Color)
void seSetLcdCursorColor(int Index, DWORD Color)
void seSetCrtCursorColor(int Index, DWORD Color)
void seSetTvCursorColor(int Index, DWORD Color)

Description:  These routines allow the user to set the either of the two user definable colors.
               The hardware cursor can be thought of as a four color image. Two of the colors cannot be changed. Displaying these two colors in a cursor image will always result in transparent and inverse video being displayed.
               The remaining two colors can be changed.
               Call seSetCursorColor() to change the cursor colors for the current active surface.
               Call seSetLcdCursorColor(), seSetCrtCursorColor(), or seSetTvCursorColor() to change the color for the surface associated with the function name.

Parameters:  

Index  Specifies which of the two application changeable colors this operation is to affect.
               Legal values for Index are 0 and 1.

Color  The new color to set as the hardware cursor color.
               The color values in the dword are arranged as follows:
               xxxx xxxx xxxR RRRR xxGG GGGG xxxB BBB
               Where x is don’t care (set to 0), R is five bits of red intensity, G is six bits of green intensity and B is five bits of blue intensity.

Return Value:  None.
void seSetCursorPixel(long x, long y, DWORD Color)
void seSetLcdCursorPixel(long x, long y, DWORD Color)
void seSetCrtCursorPixel(long x, long y, DWORD Color)
void seSetTvCursorPixel(long x, long y, DWORD Color)

Description: These functions are intended for drawing in the hardware cursor area a pixel at a time.

Call seSetCursorPixel() to set a pixel in the cursor associated with the current active surface.

Call seSetLcdCursorPixel(), seSetCrtCursorPixel(), and seSetTvCursorPixel() to set pixels in the cursor associated with the display surface indicated in the function name.

Parameters:  
x The X co-ordinate of the cursor, in pixels, at which to set the pixel color. Valid values for x range from 0 to 63.

y The Y co-ordinate of the cursor, in pixels, at which to set the pixel color. Valid values for y range from 0 to 63.

Color Specifies which of the four cursor colors set the pixel to. Valid values for Color are:

0 - to set the pixel to the solid color 0
1 - to set the pixel to the solid color 1
2 - to set the pixel to the transparent color
3 - to set the pixel to the inverted color.

Return Value: None.
void seDrawCursorLine(long x1, long y1, long x2, long y2, DWORD Color)
void seDrawLcdCursorLine(long x1, long y1, long x2, long y2, DWORD Color)
void seDrawCrtCursorLine(long x1, long y1, long x2, long y2, DWORD Color)
void seDrawTvCursorLine(long x1, long y1, long x2, long y2, DWORD Color)

Description: These routines assist in defining the cursor shape by drawing a line in the hardware cursor between the specified points.

Call seDrawCursorLine() to draw a line in the hardware cursor image associated with the current active surface.

Call seDrawLcdCursorLine(), seDrawCrtCursorLine(), or seDrawTvCursorLine() to draw a line in the hardware cursor image associated with the display surface indicated in the function name.

Parameter:

- x1 Specifies the X co-ordinate of the first endpoint of the line measured in pixels from the left edge of the cursor image.
- y1 Specifies the Y co-ordinate of the first endpoint of the line measured in pixels from the top edge of the cursor image.
- x2 Specifies the X co-ordinate of the second endpoint of the line measured in pixels from the left edge of the cursor image.
- y2 Specifies the Y co-ordinate of the second endpoint of the line measured in pixels from the top edge of the cursor image.
- Color Specifies which of the four cursor colors to draw the line with. Valid values for Color are:
  0 - to draw the line in solid color 0
  1 - to draw the line in solid color 1
  2 - to draw the line in the transparent color
  3 - to draw the line in the inverted color.

Return Value: None.
void seDrawCursorRect(long x1, long y1, long x2, long y2, DWORD color, BOOL SolidFill)
void seDrawLcdCursorRect(long x1, long y1, long x2, long y2, DWORD color, BOOL SolidFill)
void seDrawCrtCursorRect(long x1, long y1, long x2, long y2, DWORD color, BOOL SolidFill)
void seDrawTvCursorRect(long x1, long y1, long x2, long y2, DWORD color, BOOL SolidFill)

**Description:**
These routines draw rectangles on the hardware cursor surface. The rectangle may be drawn as just a border or as a solid filled area.

Call seDrawCursorRect() to draw a rectangle in the hardware cursor image associated with the current active surface.

Call seDrawLcdCursorRect(), seDrawCrtCursorRect(), or seDrawTvCursorRect() to draw a rectangle in the hardware cursor image associated with the display surface indicated by the function name.

**Parameter:**

- **x1**: The X co-ordinate for the top left corner of the rectangle measured in pixels from the left edge of the cursor image.
- **y1**: The Y co-ordinate for the top left corner of the rectangle measured in pixels from the top of the cursor image.
- **x2**: The X co-ordinate for the bottom right corner of the rectangle measured in pixels from the left edge of the cursor image.
- **y2**: The Y co-ordinate for the bottom right corner of the rectangle measured in pixels from the top edge of the cursor image.
- **Color**: Specifies which of the four cursor colors to draw the line with. Valid values for Color are:
  0 - to draw the rectangle in solid color 0
  1 - to draw the rectangle in solid color 1
  2 - to draw the rectangle to the transparent color
  3 - to draw the rectangle in the inverted color.
- **SolidFill**: Flags whether to fill the rectangle as or to only draw the border.
  Set SolidFill to FALSE (“0”) to draw only the outline of the rectangle.
  Set SolidFill to TRUE (“1”) to fill the interior of the rectangle.

**Return Value:**
None.
14.2.10 Ink Layer

The functions in this section support the hardware ink layer. These functions are nearly identical to the routines to control the hardware cursor.

The same S1D13506 uses the same hardware for both hardware cursor and ink layer which means that only the cursor or the ink layer can be active at any given time. The difference between the hardware cursor and the ink layer is that in cursor mode the image is a maximum of 64x64 pixels and can be moved around the display while in ink layer mode the image is as large as the physical size of the display and is fixed in position. Both the ink layer and hardware cursor have the same number of colors and handle these colors identically.

DWORD selInitInk(void)
DWORD selInitLcdInk(void)
DWORD selInitCrtInk(void)
DWORD selInitTvInk(void)

Description: These functions initialize the ink layer for use. The initialization includes: allocating ink layer memory, filling the ink layer image with a transparent color, and enabling the ink layer.

If memory was previously allocated for the ink layer or a hardware cursor on the surface then this memory is first released.

Call selInitInk() to initialize the ink layer for the current active surface.

Call selInitLcdInk(), selInitCrtInk(), and selInitTvInk() to initialize the ink layer for the surface indicated in the display name.

Parameters: None.

Return Value: The return value is the thirty-two bit offset in CPU address space to the start of the ink layer memory. If there is an error the return value is 0.

Note
On 16-bit DOS systems the return value must be converted into a segment:offset before use.
void seFreeInk(void)
void seFreeLcdInk(void)
void seFreeCrtInk(void)
void seFreeTvInk(void)

Description: These functions release the memory allocations made by the call to the seInitInk() calls.
Prior to calling the seFreeInk() functions the application must make a call to seEnableInk() to hide the ink layer.
Call seFreeInk() to Free the ink layer memory associated with the current active surface.
Call seFreeLcdInk(), seFreeCrtInk(), or seFreeTvInk() to free the ink layer memory associated with the surface indicated in the function name.

Parameters: None.
Return Value: None.

void seEnableInk(int Enable)
void seEnableLcdInk(int Enable)
void seEnableCrtInk(int Enable)
void seEnableTvInk(int Enable)

Description: These functions enable or disable the hardware ink layer. When enabled the ink layer will be visible and when disabled the ink layer will be hidden.
Call seEnableInk() to enable/disable the ink layer associated with the current active surface.
Call seEnableLcdInk(), seEnableCrtInk(), and seEnableTvInk() to enable/disable the hardware ink layer for the surface indicated by the function name.
Recall that the CRT and TV share the same ink layer. Enabling/disabling the ink layer for one device will affect the other display as well.

Parameters: Enable A flag indicating whether to enable or disable the ink layer.
Set Enable to FALSE (0) to disable the ink layer or set Enable to TRUE (non-0) to enable the ink layer.

Return Value: None.
DWORD seGetInkLinearAddress(void)
DWORD seGetLcdInkLinearAddress(void)
DWORD seGetCrtInkLinearAddress(void)
DWORD seGetTvInkLinearAddress(void)

Description: These routines return address for the hardware ink layer through which the application can directly access the ink layer memory.

Call seGetInkLinearAddress() to retrieve the address of the ink layer associated with the current active surface.

Call seGetLcdInkLinearAddress(), seGetCrtInkLinearAddress(), or seGetTvInkLinearAddress() to retrieve the address of the ink layer associated with the display surface indicated in the function name.

Parameters: None.

Return Value: The return value is the linear address of the hardware cursor. A linear address is the 32 bit offset in CPU address space where the application can directly read or write the hardware ink layer memory.

DWORD seGetInkOffsetAddress(void)
DWORD seGetLcdInkOffsetAddress(void)
DWORD seGetCrtInkOffsetAddress(void)
DWORD seGetTvInkOffsetAddress(void)

Description: These routines return the offset in display memory of the hardware ink layer. Using this offset an application can use HAL API calls such as seSetWriteDisplayBytes() to access the ink layer memory.

Call seGetInkOffsetAddress() to get the offset to the ink layer associated with the current active surface.

Call seGetLcdInkOffsetAddress(), seGetCrtInkOffsetAddress(), and seGetTvInkOffsetAddress() to retrieve the offset to the ink layer for the surface indicated in the function name.

Parameters: None.

Return Value: The return value is the offset, in bytes, from the start of display memory to the start of ink layer memory.
void seSetInkColor(int index, DWORD color)
void seSetLcdInkColor(int index, DWORD color)
void seSetCrtInkColor(int index, DWORD color)
void seSetTvInkColor(int index, DWORD color)

Description:
These routines allow the user to set the either of the two user definable hardware ink layer colors.

The hardware ink layer can be thought of as a four color image of which only two colors can be changed. The non-changeable colors will displays as transparent and inverted colors.

Call seSetInkColor() to change the in colors for the current active surface.

Call seSetLcdInkColor(), seSetCrtInkColor(), or seSetTvInkColor() to change the color for the surface indicated by the function name.

Parameters:
Index Index to specifies which of the two changeable colors to access. Valid values for Index are 0 and 1.

Color The new color to set as the ink layer color.

The color values in the dword are arranged as follows:
xxxx xxxx xxxR RRRR xxGG GGGG xxxB BBB

Where x is don’t care (set to 0), R is five bits of red intensity, G is six bits of green intensity and B is five bits of blue intensity.

Return Value: None.

void seSetInkPixel(long x, long y, DWORD color)
void seSetLcdInkPixel(long x, long y, DWORD color)
void seSetCrtInkPixel(long x, long y, DWORD color)
void seSetTvInkPixel(long x, long y, DWORD color)

Description:
These functions are intended for drawing on the hardware ink layer a pixel at a time.

Call seSetInkPixel() to set a pixel in the ink layer associated with the current active surface.

Call seSetLcdInkPixel(), seSetCrtInkPixel(), and seSetTvInkPixel() to set pixels in the ink layer associated with the display surface indicated in the function name.

Parameters:
x The X co-ordinate of the ink layer, in pixels, at which to set the pixel color. Valid values for x range from 0 to display width - 1.

y The Y co-ordinate of the ink layer, in pixels, a which to set the pixel color. Valid values for y range from 0 to display height - 1.

Color Specifies which of the four cursor colors set the pixel to. Valid values for Color are:

0 - to set the pixel to the solid color 0
1 - to set the pixel to the solid color 1
2 - to set the pixel to the transparent color
3 - to set the pixel to the inverted color.

Return Value: None.
void seDrawInkLine(long x1, long y1, long x2, long y2, DWORD color)
void seDrawLcdInkLine(long x1, long y1, long x2, long y2, DWORD color)
void seDrawCrtInkLine(long x1, long y1, long x2, long y2, DWORD color)
void seDrawTvInkLine(long x1, long y1, long x2, long y2, DWORD color)

Description: These routines draw lines on the hardware ink layer between two points in the specified color.

Call seDrawInkLine() to draw a line in the hardware ink layer associated with the current active surface.

Call seDrawLcdInkLine(), seDrawCrtInkLine(), or seDrawTvInkLine() to draw a line in the hardware ink layer image associated with the display surface indicated in the function name.

Parameter:

x1 Specifies the X co-ordinate of the first endpoint of the line measured in pixels from the left edge of the display.

y1 Specifies the Y co-ordinate of the first endpoint of the line measured in pixels from the top edge of the display.

x2 Specifies the X co-ordinate of the second endpoint of the line measured in pixels from the left edge of the display.

y2 Specifies the Y co-ordinate of the second endpoint of the line measured in pixels from the top edge of the display.

Color Specifies which of the four ink layer colors to draw the line with. Valid values for Color are:

0 - to draw the line in solid color 0
1 - to draw the line in solid color 1
2 - to draw the line in the transparent color
3 - to draw the line in the inverted color.

Return Value: None.
void seDrawInkRect(long x1, long y1, long x2, long y2, DWORD color, BOOL SolidFill)
void seDrawLcdInkRect(long x1, long y1, long x2, long y2, DWORD color, BOOL SolidFill)
void seDrawCrtInkRect(long x1, long y1, long x2, long y2, DWORD color, BOOL SolidFill)
void seDrawTvInkRect(long x1, long y1, long x2, long y2, DWORD color, BOOL SolidFill)

Description: These routines draw rectangles on the hardware ink layer surface. The rectangle may be
drawn as just a border or as a solid filled area.

Call seDrawInkRect() to draw a rectangle in the hardware ink layer cursor image associated with the current active surface.

Call seDrawLcdInkRect(), seDrawCrtInkRect(), or seDrawTvInkRect() to draw a rectangle in the hardware ink layer associated with the display surface indicated by the function name.

Parameter:

- **x1**: The X co-ordinate for the top left corner of the rectangle measured in pixels from the left edge of the display surface.
- **y1**: The Y co-ordinate for the top left corner of the rectangle measured in pixels from the top edge of the display surface.
- **x2**: The X co-ordinate for the bottom right corner of the rectangle measured in pixels from the left edge of the display surface.
- **y2**: The Y co-ordinate for the bottom right corner of the rectangle measured in pixels from the top edge of the display surface.
- **Color**: Specifies which of the four ink layer colors to draw the line with. Valid values for Color are:
  - 0 - to draw the rectangle in solid color 0
  - 1 - to draw the rectangle in solid color 1
  - 2 - to draw the rectangle to the transparent color
  - 3 - to draw the rectangle in the inverted color.
- **SolidFill**: Flags whether to fill the rectangle as or to only draw the border.
  - Set SolidFill to FALSE ("0") to draw only the outline of the rectangle.
  - Set SolidFill to TRUE ("1") to fill the interior of the rectangle.

Return Value: None.
14.2.11 PCI Support

The S1D13506 utilizes up to two megabytes of display memory. Addressing that much memory on Intel ISA based evaluation platforms is difficult and prone to introducing conflicts. To overcome these obstacles the standard PCI evaluation board is PCI based.

By placing the S1D13506 evaluation board on a PCI bus the issue of address space is eliminated. In addition 32 bit software can be written and debugged in a Microsoft Windows environment before being ported to an embedded platform.

In order for an application to access the S1D13506 memory and register the following two functions are provided.

DWORD seGetLinearDisplayAddress(void)
Description: This function returns the linear address for the start of physical display memory on a PCI system
Parameters: None.
Return Value: The return value is the linear address of the start of display memory. A linear address is a 32-bit offset, in CPU address space.

DWORD seGetLinearRegAddress(void)
Description: This function returns the linear address of the start of S1D13506 control registers.
Parameters: None.
Return Value: The return value is the linear address of the start of S1D13506 control registers. A linear address is a 32-bit offset, in CPU address space.
14.3 Porting LIBSE to a new target platform

Building Epson applications like a simple HelloApp for a new target platform requires 3 things, the HelloApp code, the 13506HAL library, and a some standard C functions (portable ones are encapsulated in our mini C library LIBSE).

For example, when building HELLOAPP.EXE for the x86 16-bit platform, you need the HELLOAPP source files, the 13506HAL library and its include files, and some Standard C library functions (which in this case would be supplied by the compiler as part of its run-time library). As this is a DOS .EXE application, you do not need to supply start-up code that sets up the chip selects or interrupts, etc... What if you wanted to build the application for an SH-3 target, one not running DOS?

Before you can build that application to load onto the target, you need to build a C library for the target that contains enough of the Standard C functions (like sprintf and strcpy) to let you build the application. Epson supplies the LIBSE for this purpose, but your compiler may come with one included. You also need to build the 13506HAL library for the target. This library is the graphics chip dependent portion of the code. Finally, you need to build the final application, linked together with the libraries described earlier. The following examples assume that you have a copy of the complete source code for the S1D13506 utilities, including the nmake makefiles, as well as a copy of the GNU Compiler v2.7-96q3a for Hitachi SH3. These are available on the Epson Electronics America Website at http://www.eea.epson.com.
14.3.1 Building the LIBSE library for SH3 target example

In the LIBSE files, there are three main types of files:

• C files that contain the library functions.
• assembler files that contain the target specific code.
• makefiles that describe the build process to construct the library.

The C files are generic to all platforms, although there are some customizations for targets in the form of #ifdef LCEVBSH3 code (the ifdef used for the example SH3 target Low Cost Eval Board SH3). The majority of this code remains constant whichever target you build for.

The assembler files contain some platform setup code (stacks, chip selects) and jumps into the main entry point of the C code that is contained in the C file entry.c. For our example, the assembler file is STARTSH3.S and it performs only some stack setup and a jump into the code at _mainEntry (entry.c).

In the embedded targets, printf (in file rprintf.c), putchar (putchar.c) and getch (kb.c) resolve to serial character input/output. For SH3, much of the detail of handling serial IO is hidden in the monitor of the evaluation board, but in general the primitives are fairly straightforward, providing the ability to get characters to/from the serial port.

For our target example, the nmake makefile is makesh3.mk. This makefile calls the Gnu compiler at a specific location (TOOLDIR), enumerates the list of files that go into the target and builds a .a library file as the output of the build process.

With nmake.exe in your path run:

nmake -fmakesh3.mk

14.3.2 Building a complete application for the target example

Source code for this example is available in the file 56_sh3_target.c. This file is available on the internet at www.eea.epson.com.
15 Sample Code

Example source code demonstrating programming the S1D13506 using the HAL library is available on the internet at www.eea.epson.com. Also included are three header files that may make some of the structures used clearer.

**Note:** The table above summarizes the registers for CRT/TV and LCD displays, detailing their purpose and default settings. Each register is identified by its address, function, and whether it is readable (R) or writable (W) in a memorymapped environment.
1. N/A bits should be written 0.
2. Reserved bits must be written 0.
3. MD14 on Reset = 1, MD7 on Reset = 1

### MD14 on Reset
- **Pin**: MA9, GP01, GP02
- **Value**: 1

### MD7 on Reset
- **Pin**: MA10, MA11
- **Value**: 1

### MCLK Source Select
- **Select**: 00, 01, 10, 11
- **Source**: CKI, BUSCLK, CLKI2, MCLK

### LCD PCLK Divide Select
- **Bits [1:0]**: LCD PCLK Source to LPCLK Frequency Ratio
- **Values**: 1:1, 2:1, 3:1, 4:1

### CRT/TV PCLK Divide Select
- **Bits [1:0]**: CRT/TV PCLK Source to DPCLK Frequency Ratio
- **Values**: 1:1, 2:1, 3:1

### DRAM Refresh Selection
- **Bits [2:0]**: DRAM Refresh Rate for 40MHz MCLK Source
- **Values**: 000, 001, 010, 011, 100, 101, 110, 111

### Memory Type Selection
- **Bits [1:0]**: Memory Type
- **Values**: 00, 01, 10, 11

### Memory Power Mode Selection
- **Bits [1:0]**: Power Save Mode
- **Values**: 00, 01

### Register Summary

**Register** | Description
--- | ---
REG[1E2h] | LUT ADDRESS REGISTER
REG[1E4h] | LUT DATA REGISTER
REG[1F0h] | POWER SAVE CONFIGURATION REGISTER
REG[1F1h] | POWER SAVE STATUS REGISTER
REG[1F4h] | CPU TO MEMORY ACCESS WATCHDOG TIMER REGISTER
REG[1FCh] | DISPLAY MODE REGISTER
REG[1000h] | MEDIA PLUG LCMD REGISTER
REG[1002h] | MEDIA PLUG RESERVED LCMD REGISTER
REG[1004h] | MEDIA PLUG CMD REGISTER
REG[1006h] | MEDIA PLUG RESERVED CMD REGISTER
REG[1008h] to REG[1FFFe] | even address MEDIA PLUG DATA REGISTER

### MD14 on Reset
- **Pin**: MA9, GP01, GP02
- **Value**: 01

### MD7 on Reset
- **Pin**: MA10, MA11
- **Value**: 10

### MCLK Source Select
- **Select**: 00, 01, 10, 11
- **Source**: CKI, BUSCLK, CLKI2, MCLK

### LCD PCLK Divide Select
- **Bits [1:0]**: LCD PCLK Source to LPCLK Frequency Ratio
- **Values**: 1:1, 2:1, 3:1, 4:1

### CRT/TV PCLK Divide Select
- **Bits [1:0]**: CRT/TV PCLK Source to DPCLK Frequency Ratio
- **Values**: 1:1, 2:1, 3:1

### DRAM Refresh Selection
- **Bits [2:0]**: DRAM Refresh Rate for 40MHz MCLK Source
- **Values**: 000, 001, 010, 011, 100, 101, 110, 111

### Memory Type Selection
- **Bits [1:0]**: Memory Type
- **Values**: 00, 01, 10, 11

### Memory Power Mode Selection
- **Bits [1:0]**: Power Save Mode
- **Values**: 00, 01

13506CFG

13506CFG is an interactive Windows® 9x/ME/NT/2000 program that calculates register values for a user defined S1D13506 configuration. The configuration information can be used to directly alter the operating characteristics of the S1D13506 utilities or any program built with the Hardware Abstraction Layer (HAL) library. Alternatively, the configuration information can be saved in a variety of text file formats for use in other applications.

S1D13506 Supported Evaluation Platforms

13506CFG runs on PC systems running Windows 9x/ME/NT/2000 and can modify the executable files based on the S1D13506 HAL for the following evaluation platforms:

- PC system with an Intel 80x86 processor.
- M68EC000IDP (Integrated Development Platform) board, revision 3.0, with a Motorola M68EC000 processor.
- MC68030IDP (Integrated Development Platform) board, revision 3.0, with a Motorola MC68030 processor.
- SH3-LCEVB board, revision B, with an Hitachi SH-3 HD6417780 processor.
- MPC821ADS (Applications Development System) board, revision B, with a Motorola MPC821 processor.
Installation

Create a directory for 13506cfg.exe and the S1D13506 utilities. Copy the files 13506cfg.exe and panels.def to that directory. Panels.def contains configuration information for a number of panels and must reside in the same directory as 13506cfg.exe.

Usage

13506CFG can be started from the Windows desktop or from a Windows command prompt.

To start 13506CFG from the Windows desktop, double click the program icon or the link icon if one was created during installation.

To start 13506CFG from a Windows command prompt, change to the directory 13506cfg.exe was installed to and type the command 13506cfg.

The basic procedure for using 13506CFG is:

1. Start 13506CFG as described above.
2. Open an existing file to serve as a starting reference point (this step is optional).
3. Modify the configuration. For specific information on editing the configuration, see “13506CFG Configuration Tabs” on page 7.
4. Save the new configuration. The configuration information can be saved in two ways; as an ASCII text file or by modifying the executable image on disk.

   Several ASCII text file formats are supported. Most are formatted C header files used to build display drivers or standalone applications.

   Utility files based on the Hardware Abstraction Layer (HAL) can be modified directly by 13506CFG.
13506CFG Configuration Tabs

13506CFG provides a series of tabs which can be selected at the top of the main window. Each tab allows the configuration of a specific aspect of S1D13506 operation.

The tabs are labeled “General”, “Preference”, “Memory”, “Clocks”, “Panel”, “CRT/TV”, and “Registers”. The following sections describe the purpose and use of each of the tabs.

General Tab

The General tab contains S1D13506 evaluation board specific information. The values presented are used for configuring HAL based executable utilities. The settings on this tab specify where in CPU address space the registers and display buffer are located.

Decode Addresses

Selecting one of the listed evaluation platforms changes the values for the “Register address” and “Display buffer address” fields. The values used for each evaluation platform are examples of possible implementations as used by the Epson S1D13506 evaluation board.

If your hardware implementation differs from the addresses used, select the User-Defined option and enter the correct addresses for “Register address” and “Display buffer address”.

NOTE: The decoding of the S1D13506 physical addresses depends on your particular hardware implementation. The selection of Platform Types above reflect only one of many possible implementations for each platform.
Register Address
The physical address of the start of register decode space (in hexadecimal).
This field is automatically set according to the Decode Address unless the “User-Defined” decode address is selected.

Display Buffer Address
The physical address of the start of display buffer decode space (in hexadecimal).
This field is automatically set according to the Decode Address unless the “User-Defined” decode address is selected.

Note
When “Epson S5U13506B00B/B00C Evaluation Board” is selected, the register and display buffer addresses are blanked because the evaluation board uses the PCI interface and the decode addresses are determined by the system BIOS during boot-up.

If using the S1D13506 Evaluation Board on a PCI based platform, both Windows and the S1D13XXX device driver must be installed. For further information on the S1D13XXX device driver, see the S1D13XXX Windows 9x/NT/2000 Device Driver Installation Guide, document number X00A-E-003-xx.
Preferences Tab

The Preference tab contains settings pertaining to the initial display state. During runtime the display or color depth may be changed.

Initial Display        Sets which display device is used for the initial display.

Selections made on the CRT/TV tab may cause selections on this tab to be grayed out. The selections “None” and “Panel” are always available.

Panel SwivelView       The S1D13506 SwivelView feature is capable of rotating the image displayed on an LCD panel 90°, 180°, or 270° in a clockwise direction. This sets the initial orientation of the panel.

This setting is greyed out when any display device other than “Panel” is selected as the Initial Display.

Panel Color Depth      Sets the initial color depth on the LCD panel.

CRT/TV Color Depth    Sets the initial color depth on the CRT or TV display.
Memory Tab

The Memory tab contains settings that control the configuration of the DRAM used for the S1D13506 display buffer.

**Note**
The DRAM memory type and access time determines the optimal memory clock (MCLK). See “Clocks Tab” on page 12 for an explanation on how to determine the optimal memory clock.

**Memory Configuration**
These four settings must be configured based on the specification of the DRAM being used. For each of the following settings refer to the DRAM manufacturer’s specification, unless otherwise noted.

- **Access Time**
  Selects the access time of the DRAM.

  The S1D13506 evaluation boards use 50ns DRAM.

- **Memory Type**
  Selects the memory type, either Extended Data Out (EDO) or Fast Page Mode (FPM).

  The S1D13506 evaluation boards use EDO DRAM.
<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WE# Control</td>
<td>Selects the WE# control used for the DRAM. DRAM uses one of two methods of control when writing to memory. These methods are referred to as 2-CAS# and 2-WE#. The S5U13506 evaluation boards use DRAM requiring the 2-CAS# method.</td>
</tr>
<tr>
<td>Refresh Time</td>
<td>Selects the number of ms required to refresh 256 rows of DRAM.</td>

</tbody>
</table>
The Clocks tab is intended to simplify the selection of input clock frequencies and the source of internal clocking signals. For further information regarding clocking and clock sources, refer to the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx.

In automatic mode the values for CLKI and CLKI2 are calculated based on selections made for LCD and CRT/TV timings from the “Panel” and “CRT/TV” tabs. In this mode, the required frequencies for the input clocks are displayed in blue in the “Auto” section of each group. It is the responsibility of the system designer to ensure that the correct CLKI frequencies are supplied to the S1D13506.

Making a selection other than “Auto” indicates that the values for CLKI or CLKI2 are known and are fixed by the system design. Options for LCD and CRT/TV frame rates are limited to ranges determined by the clock values.

**Note**
Changing clock values may modify or invalidate Panel or CRT/TV settings. Confirm all settings on these two tabs after changing any clock settings.

**Note**
If the same source clock is selected for use by both CRT/TV and LCD panels, the available LCD pixel clock selections are limited due to more stringent CRT/TV timings.
The S1D13506 may use as many as three input clocks or as few as one. The more clocks used the greater the flexibility of choice in display type and memory speed.

**CLKI**

This setting determines the frequency of CLKI. CLKI is typically used for the panel and CRT/TV pixel clocks.

Select “Auto” to have the CLKI frequency determined automatically based on settings made on other configuration tabs. After completing the other configurations, the required CLKI frequency will be displayed in blue in the Auto section.

If the CLKI frequency must be fixed to a particular rate, set this value by selecting a preset frequency from the drop down list or entering the desired frequency in MHz.

**CLKI2**

This setting determines the frequency of CLKI2. If the MediaPlug interface is required, CLKI2 is typically used as the clock source.

Select “Auto” to have the CLKI2 frequency determined automatically based on settings made on other configuration tabs. After completing the other configurations, the required CLKI2 frequency will be displayed in blue in the Auto section.

If the CLKI2 frequency must be fixed to a particular rate, set this value by selecting a preset frequency from the drop down list or entering the desired frequency in MHz.

**BUSCLK**

This setting determines the frequency of the bus interface clock (BUSCLK). This value is required for calculating internal divisors which will yield the best performance.

The BUSCLK frequency must be fixed to a particular rate. Set this value by selecting a preset frequency from the drop down list or entering the desired frequency in MHz.

**BCLK=BUSCLK/2**

Indicates the BCLK to BUSCLK ratio. This ratio is set at RESET# by the configuration pin CONF5.

Under normal circumstances BCLK = BUSCLK. This option is only for configuring Toshiba/Philips interfaces when DCLKOUT is connected to the S1D13506 BUSCLK signal.
### LCD PCLK

These settings select the signal source and input clock divisor for the panel pixel clock (LCD PCLK).

- **Source**
  Selects the LCD PCLK source. Possible sources include CLKI, CLKI2, BUSCLK or MCLK. Typically the LCD PCLK is derived from CLKI.

- **Divide**
  Specifies the divide ratio for the clock source signal.

  Selecting “Auto” for the divisor allows the configuration program to calculate the best clock divisor. Unless a very specific clocking is being specified, it is best to leave this setting on “Auto”.

- **Timing**
  This field shows the actual LCD PCLK used by the configuration process.

### CRT/TV PCLK

These settings select the signal source and input clock divisor for the CRT/TV pixel clock (CRT/TV PCLK).

- **Source**
  Selects the CRT/TV PCLK source. Possible sources include CLKI, CLKI2, BUSCLK or MCLK. Typically the CRT/TV PCLK is derived from CLKI.

- **Divide**
  Specifies the divide ratio for the clock source signal.

  Selecting “Auto” for the divisor allows the configuration program to calculate the best clock divisor. Unless a very specific clocking is required, it is best to leave this setting on “Auto”.

- **Timing**
  This field shows the actual CRT/TV PCLK used by the configuration process.
MCLK

These settings select the signal source and input clock divisor for the memory clock (MCLK). MCLK should be set based on the type and speed of DRAM as follows.

<table>
<thead>
<tr>
<th>Memory Type</th>
<th>Optimal Memory Clock (MCLK)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>50ns</td>
</tr>
<tr>
<td>EDO</td>
<td>40MHz</td>
</tr>
<tr>
<td>FPM</td>
<td>--</td>
</tr>
</tbody>
</table>

Source

Selects the MCLK source. Possible sources include CLKI or BUSCLK. Typically MCLK is derived from BUSCLK.

Divide

Specifies the divide ratio for the clock source signal. Unless the MCLK source frequency is very high, resulting in more than a 50MHz MCLK, this ratio should be set at 1:1.

Timing

This field shows the actual MCLK frequency used by the configuration process.

MediaPlugCLK

These settings select the signal source and input clock divide for the MediaPlug clock (MediaPlugCLK).

Source

Selects the MediaPlug clock source.

Divide

Selects the divide ratio for the MediaPlug clock source.

Timing

This field shows the actual MediaPlugCLK frequency used by the configuration process.
Panel Tab

The S1D13506 supports many panel types. This tab allows configuration of most panel settings such as panel dimensions, type and timings.

Panel Type

Selects between passive (STN) and active (TFT) panel types. Select TFT for TFT compatible D-TFD panel types.

Several options may change or become unavailable when the STN/TFT setting is switched. Therefore, confirm all settings on this tab after the Panel Type is changed.

EL Support

Enable Electro-Luminescent panel support. This option is only available when the selected panel type is STN.
<table>
<thead>
<tr>
<th>Configuration Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Panel Data Width</td>
<td>Selects the panel data width. Panel data width is the number of bits of data transferred to the LCD panel on each clock cycle and shouldn’t be confused with color depth which determines the number of displayed colors. When the panel type is STN, the available options are 4 bit, 8 bit, and 16 bit. When the panel type is TFT the available options are 9 bit, 12 bit, and 18 bit.</td>
</tr>
<tr>
<td>Single / Dual</td>
<td>Selects between a single or dual panel. When the panel type is TFT, “Single” is automatically selected and the “Dual” option is grayed out.</td>
</tr>
<tr>
<td>Disable Dual Panel Buffer</td>
<td>The Dual Panel Buffer is used with dual STN panels to improve image quality by buffering display data in a format directly usable by the panel. This option is primarily intended for testing purposes. It is not recommended that the Dual Panel Buffer be disabled as a reduction of display quality will result.</td>
</tr>
<tr>
<td>Mono / Color</td>
<td>Selects between a monochrome or color panel.</td>
</tr>
<tr>
<td>Format 2</td>
<td>Selects color STN panel format 2. This option is specifically for configuring 8-bit color STN panels. See the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx, for description of format 1 / format 2 data formats. Most new panels use the format 2 data format.</td>
</tr>
<tr>
<td>FPLINE Polarity</td>
<td>Selects the polarity of the FPLINE pulse. Refer to the panel specification for the correct polarity of the FPLINE pulse.</td>
</tr>
<tr>
<td>FPFRAME Polarity</td>
<td>Selects the polarity of the FPFRAME pulse. Refer to the panel specification for the correct polarity of the FPFRAME pulse.</td>
</tr>
</tbody>
</table>
| Panel Dimensions            | These fields specify the panel width and height. A number of common widths and heights are available in the selection boxes. If the width/height of your panel is not listed, enter the actual panel dimensions into the edit field. Manually entered panel widths must be a multiple of
eight pixels. If a manually entered panel width is not a multiple of eight pixels a notification box appears and 13506CFG rounds up the value to the next allowable width.

Non-display period

It is recommended that these automatically generated non-display values be used without adjustment. However, manual adjustment may be useful in fine tuning the non-display width and the non-display height.

As a general rule passive LCD panels and some CRTs are tolerant of a wide range of non-display times. Active panels, TVs and some CRTs are far less tolerant of changes to the non-display period.

Frame Rate

Select the desired frame rate (in Hz) from the drop-down list. The values in the list are the range of possible frame rates using the currently selected pixel clock. To change the range of frame rates, select a different Pixel Clock rate (in MHz).

Panel dimensions are fixed therefore frame rate can only be adjusted by changing either PCLK or non-display period values. Higher frame rates correspond to smaller horizontal and vertical non-display values, or higher frequencies.

Pixel Clock

Select the desired Pixel Clock (in MHz) from the drop-down list. The range of frequencies displayed is dependent on settings selected on the Clocks tab.

For example:
If CLKI is chosen to be Auto and LCD PCLK is sourced from CLKI on the Clocks tab, then the range for Pixel Clock will range from 1.5 MHz to 80 MHz.

Selecting a fixed LCD PCLK on the Clocks tab, say 25.175 MHz, will result in only four selections: 6.293, 8.392, 12.587, and 25.175 MHz. (these frequencies represent the four possible frequencies from a fixed 25.175 MHz input clock divided by the PCLK divider).

TFT/FPLINE (pixels)

These settings allow fine tuning of the TFT/D-TFT line pulse parameters and are only available when the selected panel type is TFT. Refer to S1D13506 Hardware Functional Specification, document number X25B-A-001-xx for a complete description of the FPLINE pulse settings.
<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start pos</td>
<td>Specifies the delay (in pixels) from the start of the horizontal non-display period to the leading edge of the FPLINE pulse.</td>
</tr>
<tr>
<td>Pulse Width</td>
<td>Specifies the delay (in pixels) from the start of the horizontal non-display period to the leading edge of the FPLINE pulse.</td>
</tr>
<tr>
<td>TFT/FPFRAME (lines)</td>
<td>These settings allow fine tuning of the TFT/D-TFT frame pulse parameters and are only available when the selected panel type is TFT. Refer to S1D13506 Hardware Functional Specification, document number X25B-A-001-xx, for a complete description of the FPFRAME pulse settings.</td>
</tr>
<tr>
<td>Start pos</td>
<td>Specify the delay (in lines) from the start of the vertical non-display period to the leading edge of the FPFRAME pulse.</td>
</tr>
<tr>
<td>Pulse width</td>
<td>Specifies the pulse width (in lines) of the FPFRAME output signal.</td>
</tr>
<tr>
<td>Predefined Panels</td>
<td>13506CFG uses a file (panels.def) which lists various panel manufacturers recommended settings. If the file panels.def is present in the same directory as 13506cfg.exe, the settings for a number of predefined panels are available in the drop-down list. If a panel is selected from the list, 13506CFG loads the predefined settings contained in the file.</td>
</tr>
</tbody>
</table>
CRT/TV Tab

The CRT/TV tab configures settings specific to CRT/TV display devices.

Display Selection

Select the type of alternate display from: CRT, TV/NTSC, or TV/PAL.

Note that CRT and TV cannot be simultaneously selected.

Display Dimensions

Selects the resolution and frame rate from the drop-down list. The available selections vary based on selections made in the Clocks tab and which Display Selection is chosen on this tab (CRT, TV/NTSC, TV/PAL).

If no selections are available, the CRT/TV pixel clock settings on the Clocks tab must be changed.
TV Filters

When displaying computer images on a TV, several image distortions may arise. The S1D13506 incorporates three filters which reduce these distortions. Each filter type is enabled by checking the associated box.

Luminance

The luminance filter adjusts the brightness of the TV and reduces the “rainbow-like” colors at the boundaries between sharp luminance transitions. This filter is most useful for composite video output.

Chrominance

The chrominance filter adjusts the color of the TV and reduces the “ragged edges” seen at the boundaries between sharp color transitions. This filter is most useful for composite video output.

Flicker

The “flickering” effect seen on interlaced displays is caused by sharp vertical image transitions such as window edges. Turning on the anti-flicker filter averages adjacent lines on the TV display to reduce flickering.

TV Output

Selects the TV output format: Composite or S-Video.

CRT DAC output level

When the CRT is active, the CRT DAC Output Level can be used to double values output to the DAC. This would normally result in very bright colors on the display, but if IREF is reduced at the same time the display will remain at its intended brightness and power consumption is reduced.

For more information on setting the CRT DAC output level, see the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx.

Note

For CRT operations, 13506CFG supports VESA timings only. For TV operations, 13506CFG supports NTSC and PAL timings only. Overriding these register values on the Registers page may cause the CRT or TV to display incorrectly.
Registers Tab

The Registers tab allows viewing and direct editing the S1D13506 register values.

Scroll up and down the list of registers and view their configured value. Individual register settings may be changed by double-clicking on the register in the listing. **Manual changes to the registers are not checked for errors, so caution is warranted when directly editing these values.** It is strongly recommended that the *S1D13506 Hardware Functional Specification*, document number X25B-A-001-xx be referred to before making manual register settings.

Manually entered values may be changed by 13506CFG if further configuration changes are made on the other tabs. In this case, the user is notified of the changes when they return to the registers tab.

**Note**

Manual changes to the registers may have unpredictable results if incorrect values are entered.
13506CFG Menus

The following sections describe each of the options in the File and Help menus.

Open...

From the Menu Bar, select “File”, then “Open...” to display the Open File Dialog Box.

The Open option allows 13506CFG to open files containing HAL configuration information. When 13506CFG opens a file it scans the file for an identification string, and if found, reads the configuration information. This may be used to quickly arrive at a starting point for register configuration. The only requirement is that the file being opened must contain a valid S1D13506 HAL library information block.

13506CFG supports a variety of executable file formats. Select the file type(s) 13506CFG should display in the Files of Type drop-down list and then select the filename from the list and click on the Open button.

Note

13506CFG is designed to work with utilities programmed using a given version of the HAL. If the configuration structure contained in the executable file differs from the version 13506CFG expects the Open will fail and an error message is displayed. This may happen if the version of 13506CFG is substantially older, or newer, than the file being opened.
Save

From the Menu Bar, select “File”, then “Save” to initiate the save action. The Save menu option allows a fast save of the configuration information to a file that was opened with the Open menu option.

**Note**
This option is only available once a file has been opened.

**Note**
13506cfg.exe can be configured by making a copy of the file 13506cfg.exe and configuring the copy. It is not possible to configure the original while it is running.

Save As...

From the Menu Bar, select “File”, then “Save As...” to display the Save As Dialog Box.

```
“Save as” is very similar to Save except a dialog box is displayed allowing the user to name the file before saving.

Using this technique a tester can configure a number of files differing only in configuration information and name (e.g. BMP60Hz.EXE, BMP72Hz.EXE, BMP75Hz.EXE where only the frame rate changes in each of these files).

**Note**
When “Save As” is selected then an exact duplicate of the file as opened by the “Open” option is created containing the new configuration information.
```
Configure Multiple

After determining the desired configuration, “Configure Multiple” allows the information to be saved into one or more executable files built with the HAL library.

From the Menu Bar, select “File”, then “Configure Multiple” to display the Configure Multiple Dialog Box. This dialog box is also displayed when a file(s) is dragged onto the 13506CFG window.

The left pane lists files available for configuration; the right pane lists files that have been selected for configuration. Files can be selected by clicking the “Add” or “Add All” buttons, double clicking any file in the left pane, or by dragging the file(s) from Windows Explorer.

Selecting “Show all files” displays all files in the selected directory, whereas selecting “Show conf. files only” will display only files that can be configured using 13506CFG.

The configuration values can be saved to a specific EXE file for Intel platforms, or to a specific S9 or ELF file for non-Intel platforms. The file must have been compiled using the 13506 HAL library.

Checking “Preserve Physical Addresses” instructs 13506CFG to use the register and display buffer address values the files were previously configured with. Addresses specified in the General Tab are discarded. This is useful when configuring several programs for various hardware platforms at the same time. For example, if configuring PCI, MPC and IDP based programs at the same time for a new panel type, the physical addresses for each are retained. This feature is primarily intended for the test lab where multiple hardware configurations exist and are being tested.
After determining the desired configuration, “Export” permits the user to save the register information as a variety of ASCII text file formats. The following is a list and description of the currently supported output formats:

- a C header file for use in writing HAL library based applications.
- a C header file which lists each register and the value it should be set to.
- a C header file for use in developing Window CE display drivers.
- a C header file for use in developing display drivers for other operating systems such as Linux, QNX, and VxWorks UGL or WindML.
- a comma delimited text file containing an offset, a value, and a description for each S1D13506 register.

After selecting the file format, click the “Export As...” button to display the file dialog box which allows the user to enter a filename before saving. Before saving the configuration file, clicking the “Preview” button starts Notepad with a copy of the configuration file about to be saved.

When the C Header File for S1D13506 WinCE Drivers option is selected as the export type, additional options are available and can be selected by clicking on the Options button. The options dialog appears as:
Enable Tooltips

Tooltips provide useful information about many of the items on the configuration tabs. Placing the mouse pointer over nearly any item on any tab generates a popup window containing helpful advice and hints.

To enable/disable tooltips check/uncheck the “Tooltips” option form the “Help” menu.

Note
   Tooltips are enabled by default.

ERD on the Web

This “Help” menu item is actually a hotlink to the Epson Research and Development website. Selecting “Help” then “ERD on the Web” starts the default web browser and points it to the ERD product web site.

The latest software, drivers, and documentation for the S1D13506 is available at this website.

About 13506CFG

Selecting the “About 13506CFG” option from the “Help” menu displays the about dialog box for 13506CFG. The about dialog box contains version information and the copyright notice for 13506CFG.

Comments

- On any tab particular options may be grayed out if selecting them would violate the operational specification of the S1D13506 (i.e. Selecting extremely low CLK frequencies on the Clocks tab may result in no possible CRT/TV options. Selecting TFT or STN on the Panel tab enables/disables options specific to the panel type).

- The file panels.def is a text file containing operational specifications for several supported, and tested, panels. This file can be edited with any text editor.

- 13506CFG allows manually altering register values. The manual changes may violate memory and LCD timings as specified in the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx. If this is done, unpredictable results may occur. Epson Research and Development, Inc. does not assume liability for any damage done to the display device as a result of configuration errors.
THIS PAGE LEFT BLANK
13506SHOW

13506SHOW is designed to demonstrate and test some of the S1D13506 display capabilities. The program can cycle through all color depths and display a pattern showing all available colors or shades of gray. Alternately, the user can specify a color depth and display configuration. 13506SHOW supports SwivelView™ (90°, 180°, and 270° hardware rotation of the display image).

The 13506SHOW demonstration program must be configured and/or compiled to work with your hardware platform. The program 13506CFG.EXE can be used to configure 13506SHOW. Consult the 13506CFG users guide, document number X25B-B-001-xx, for more information on configuring S1D13506 utilities.

This software is designed to work in both embedded and personal computer (PC) environments. For the embedded environment, it is assumed that the system has a means of downloading software from the PC to the target platform. Typically this is done by serial communications, where the PC uses a terminal program to send control commands and information to the target processor. Alternatively, the PC can program an EPROM, which is then placed in the target platform. Some target platforms can also communicate with the PC via a parallel port connection, or an Ethernet connection.

S1D13506 Supported Evaluation Platforms

13506SHOW supports the following S1D13506 evaluation platforms:

- PC system with an Intel 80x86 processor.
- M68EC000IDP (Integrated Development Platform) board, revision 3.0, with a Motorola M68EC000 processor.
- MC68030IDP (Integrated Development Platform) board, revision 3.0, with a Motorola MC68030 processor.
- SH3-LCEVB board, revision B, with an Hitachi SH-3 HD6417780 processor.
- MPC821ADS (Applications Development System) board, revision B, with a Motorola MPC821 processor.

Installation

**PC platform:**

Copy the file 13506show.exe to a directory specified in the path (e.g. PATH=C:\13506).

**Embedded platform:**

Download the program 13506show to the system.
Usage

PC Platform

At the prompt, type:

13506SHOW [/a] [bl=n] [bc=n] [ds=n | ds=?] [/g] [/noinit] [/r90 | /r180 | /r270] [/read] [/s] [/write] [/?]

Embedded platform

Execute 13506show and type the command line argument at the prompt.

Where:

/a cycles through all video modes automatically.
bl=n shows the LCD display at a user specified color depth (bpp) where n = (4, 8, 15, 16).
bc=n shows the CRT/TV display at a user specified color depth (bpp) where n = (4, 8, 15, 16).
ds=n selects display surfaces (see Section , “Display Surfaces” on page 5).
ds=? shows the available display surfaces (see Section , “Display Surfaces” on page 5).
g shows a grid on the image.
noinit skips full register initialization. Only registers used for changing the color depth (bpp), selecting the memoryregisters and programming the clock synthesizer are updated. Additionally, some registers are read to determine information such as display size and type (LCD, CRT, TV).
r90 SwivelView™ 90°, clockwise hardware rotation of LCD image by 90 degrees
r180 SwivelView™ 180°, clockwise hardware rotation of LCD image by 180 degrees
r270 SwivelView™ 270°, clockwise hardware rotation of LCD image by 270 degrees
Display Surfaces

A surface is a block of memory assigned to one or more physical display devices. 13506SHOW provides 7 display surfaces (0-6) which cover the possible combinations of display types. Table 1: “Display Surfaces” lists the predefined display surfaces that may be selected.

<table>
<thead>
<tr>
<th>Display Surfaces (ds=)</th>

</tr>
</tbody>
</table>

Display surfaces 0 through 2 each display data from a single memory block to an individual display device (LCD, CRT, or TV).

Display surfaces 3 and 4 output to two separate display devices, but generate the output from the same memory block. This may be useful when the same image is to be displayed on both display devices. It also reduces the total amount of display memory required.

Display surfaces 5 and 6 output to two separate devices from different memory blocks. This allows two completely different images to be displayed at the same time. When using display surfaces 5 or 6, some combinations of display modes with a high resolution and/or high color depth may not be supported within a 2MB display buffer.
13506SHOW Examples

13506SHOW is designed to both demonstrate and test some of the features of the S1D13506. The following examples show how to use the program in both instances.

Using 13506SHOW For Demonstration

1. To show color patterns which must be manually stepped through, type the following:

   13506SHOW

   The program displays the default color depth and display surface as selected in 13506CFG. Press any key to go to the next screen. Once all screens are shown the program exits. To exit the program immediately press the Esc key.

2. To show color patterns which automatically step through all color depths beginning with the default color depth (as selected in 13506CFG), type the following:

   13506SHOW /a

   The program will display the default color depth. Each screen is shown for approximately 1 second before the next screen is automatically shown. The program exits after the last screen is shown. To exit the program immediately press CTRL+BREAK.

3. To show a color pattern for a specific color depth on the LCD, type the following:

   13506SHOW bl=[mode]

   where mode = 4, 8, 15, or 16.

   The program displays the requested screen and then exits.

Note

If a monochrome LCD panel is used, the image is formed using only the green component of the Look-Up Table.

4. To show a color pattern for a specific color depth on the CRT, type the following:

   13506SHOW bc=[mode]

   where mode = 4, 8, 15, or 16.

   The program display the requested screen and then exits.
5. To show the color patterns in SwivelView™ 90° mode, type the following:

13506SHOW /r90

The program will display the default color depth (as selected in 13506CFG). Press any key to go to the next screen. Since SwivelView™ 90° is limited to color depths of 8, 15 and 16 bpp the program exits. To exit the program immediately press the Esc key.

The “/r90”, “/r180”, and “/r270” switches can be used in combination with other command line switches.

6. To show solid vertical stripes, type the following:

13506SHOW /s

The program will display the default color depth (as selected in 13506CFG). Press any key to go to the next screen. Once all screens are shown the program exits. To exit the program immediately press the Esc key.

The “/s” switch can be used in combination with other command line switches.

Using 13506SHOW For Testing

1. To show a test grid over the 8 bpp color pattern on an LCD, type the following:

13506SHOW bl=8 /g

The program will display the 8 bpp color pattern overlaid with a white grid 20 pixels wide and then exit. The grid makes it obvious if the image is shifted or if pixels are missing. Note the grid is not aligned with the color pattern, therefore the color boxes will not match the grid boxes.

The “/g” switch can be used in combination with other command line switches.

2. To test background memory reads to the CRT, type the following:

13506SHOW bc=16 /read

The program will test screen reads. If there is a problem with memory access, the displayed pattern will appear different than when the “/read” switch is not used. If there is a problem, check the configuration parameters of 13506SHOW using the utility 13506CFG. See the 13506CFG user guide, document number X25B-B-001-xx, for more information.

The “/read” switch should be used in combination with the “b=” setting, otherwise the test will always start with the default color depth (as selected in 13506CFG). To exit the program after using “/read”, press the Esc key and wait for a couple of seconds (the keystroke is checked after reading a full screen).
Comments

- If 13506SHOW is started without defining the color depth, the program automatically cycles through the available color depths from highest to lowest. The first color depth shown is the default color depth value saved to 13506SHOW using 13506CFG. This approach avoids showing color depths not supported by a given hardware configuration.

- 13506SHOW checks if the display(s) selected from the DS= option have been previously configured by 13506CFG. If these display(s) have not been configured, 13506SHOW displays an error message. For example, if the system is configured for the CRT, an error is displayed if the user selects the TV with the DS= option.

- If the DS= option is used to combine two displays of different resolutions into the same surface, the program will display an error message.

- 13506SHOW cannot show a greater color depth than the display allows.

- SwivelView™ (/r90, /r270) is available only for color depths of 8, 15, and 16 bpp.

- SwivelView™ (/r180) is available for color depths of 4, 8, 15, and 16 bpp.

- If the “bl=” or “bc=” options are not used, 13506SHOW will cycle through all available color depths.
Program Messages

ERROR: Could not detect S1D13506.
The ID register did not indicate the presence of the 13506.

ERROR: Could not map memory from evaluation board to host platform.
This message should only be shown for DOS platforms. In this case the DOS extender could not be
initialized, or was unable to get the linear address of the display memory.

ERROR: In the given display surface configuration, the user must select the same BPP for
both LCD and CRT/TV.
When two displays are using an image from the same display memory block, both displays must be
configured for the same color depth (bpp).

ERROR: Invalid display surface number.
The "ds=" command line option included an invalid value. The parameter "ds=?" lists the valid
numbers.

ERROR: LCD and CRT resolutions must be identical.
LCD: (width, height)
CRT: (width, height)
When the LCD and CRT are using an image from the same display memory block, both displays
must be the same resolution.

ERROR: LCD and TV resolutions must be identical.
LCD: (width, height)
TV: (width, height)
When the LCD and TV are using an image from the same display memory block, both displays
must be the same resolution.

ERROR: LCD must be in landscape mode.
The LCD panel must be configured for SwivelView 0° mode (landscape) if both the LCD display
and CRT/TV are active.

ERROR: Not enough display buffer memory.
There was insufficient display buffer memory for the given configuration. Memory requirements
depend on:

- the display resolution(s).
- the bit-per-pixel depth(s).
- whether a half-frame buffer is required.
- the number of displays active (LCD or LCD and CRT/TV).
ERROR: Not enough memory for LCD/CRT/TV in 4/8/16 bits-per-pixel.
13506SHOW is unable to change the color depth due to insufficient display buffer memory. Memory requirements depend on:

- the display resolution(s).
- the bit-per-pixel depth(s).
- whether a half-frame buffer is required.
- the number of displays active (LCD or LCD and CRT/TV).

ERROR: PCI bridge adapter not found.
The Windows PCI driver did not find the PCI Bridge Adapter.

ERROR: PCI driver not found.
The Windows PCI driver is not loaded.

ERROR: Program not configured for LCD/CRT/TV. Run 13506CFG and configure for LCD/CRT/TV.
The program was configured by 13506CFG for a display device that is not available. This typically occurs if the wrong command line was entered for the current configuration.

WARNING: CLKI frequency not in HAL table. Program assumes that external oscillator is used.
WARNING: CLKI2 frequency not in HAL table. Program assumes that external oscillator is used.
The correct frequency was not found in the HAL table used to program the clock synthesizer. An external oscillator may be in use. This warning message will not stop the program.

WARNING: CRT/TV only available in LANDSCAPE mode.
SwivelView™ is only available on LCD only configurations.

ERROR: b= option cannot be used with /noinit.
The command line options b= and /noinit are contradictory, since b= instructs the program to change the color depth and /noinit indicates that no register changes are to be made.

ERROR: Continual screen read will not work with the /a switch.
ERROR: Continual screen write will not work with the /a switch.
The /a switch automatically cycles through the different color depths, whereas the continual screen read/write goes into an infinite loop to read/write memory.

ERROR: Do not select 4 BPP LCD in SwivelView™ 90 or SwivelView™ 270 degrees.
SwivelView™ 90 and SwivelView™ 270 are available only in 8 and 16 bits-per-pixel modes.
THIS PAGE LEFT BLANK
13506PLAY

13506PLAY is a diagnostic utility which allows the user to read/write to all the S1D13506 Registers, Look-Up Tables and Display Buffer. 13506PLAY is similar to the DOS DEBUG program; commands are received from the standard input device, and output is sent to the standard output device (console for Intel, terminal for embedded platforms). This utility requires the target platform to support standard IO (stdio).

13506PLAY commands can be entered interactively by a user, or be executed from a script file. Scripting is a powerful feature which allows command sequences to be used repeatedly without re-entry.

The 13506PLAY diagnostic utility must be configured and/or compiled to work with your hardware platform. The program 13506CFG.EXE can be used to configure 13506PLAY. Consult the 13506CFG users guide, document number X25B-B-001-xx, for more information on configuring S1D13506 utilities.

This software is designed to work in both embedded and personal computer (PC) environments. For the embedded environment, it is assumed that the system has a means of downloading software from the PC to the target platform. Typically this is done by serial communications, where the PC uses a terminal program to send control commands and information to the target processor. Alternatively, the PC can program an EPROM, which is then placed in the target platform. Some target platforms can also communicate with the PC via a parallel port connection, or an Ethernet connection.

S1D13506 Supported Evaluation Platforms

13506PLAY supports the following S1D13506 evaluation platforms:

- PC with an Intel 80x86 processor running Windows '95/'98/NT.
- M68EC000IDP (Integrated Development Platform) board, revision 3.0, with a Motorola M68EC000 processor.
- MC68030IDP (Integrated Development Platform) board, revision 3.0, with a Motorola MC68030 processor.
- SH3-LCEVB board, revision B, with an Hitachi SH-3 HD6417780 processor.
- MPC821ADS (Applications Development System) board, revision B, with a Motorola MPC821 processor.
Installation

PC platform

Copy the file 13506play.exe to a directory in the path (e.g. PATH=C:\S1D13506).

Embedded platform

Download the program 13506play to the system.

Usage

PC platform

At the prompt, type:

13506play [/?]

Where:

/? displays program version information.

Embedded platform

Execute 13506play and at the prompt, type the command line argument.

Where:

/? displays program version information.
Commands

The following commands are designed to be used from within the 13506PLAY program. However, simple commands can also be executed from the command line. If a command with multiple arguments is executed from the command line, it must be enclosed in double quotes (e.g. 13506play “f 0 1FFFFF AB” q).

CLKI [?] iFreq
Selects a preset clock frequency (MHz) for CLKI. If the “?” option is used, the current CLKI frequency is displayed.
Where:

? Displays a list of available frequencies for CLKI (MHz).
iFreq Sets CLKI to a preset frequency (MHz) specified by iFreq.

CLKI2 [?] iFreq
Selects a preset clock frequency (MHz) for CLKI2. If the “?” option is used, the current CLKI2 frequency is displayed.
Where:

? Displays a list of available frequencies for CLKI2 (MHz).
iFreq Sets CLKI2 to a preset frequency (MHz) specified by iFreq.

CW word
Sends a 24-bit hexadecimal value to the programmable clock. Note that the programmable clock documentation uses the term “word” to describe the 24-bit value. The use of “word” does not imply a 16-bit value in this case.

F addr addr data...
Fills a specified address range with 8-bit data (bytes).
Where:

addr Address range to be filled (hex).
data Data to be written (hex). Data can be a list of bytes that will be repeated for the duration of the fill. To use decimal values, attach a “t” suffix to the value. (e.g. 100t is 100 decimal)

FD addr addr data...
Fills a specified address range with 32-bit data (dwords).
Where:

addr Address range to be filled (hex).
data Data to be written (hex). Data can be a list of dwords that will be repeated for the duration of the fill. To use decimal values, attach a “t” suffix to the value. (e.g. 100t is 100 decimal)
FW addr addr data...
Fills a specified address range with 16-bit data (words).
Where:
  addr Address range to be filled (hex).
  data Data to be written (hex). Data can be a list of words that will be repeated for the duration of the fill. To use decimal values, attach a “t” suffix to the value. (e.g. 100t is 100 decimal).

H [lines]
Sets the number of lines of data that will be displayed at a time. The display will be halted after the specified number of lines. Setting the number of lines to 0 will disable the halt function and allow the data to continue displaying until all data has been shown.
Where:
  lines Number of lines that will be shown before halting the displayed data (decimal value).

I [?] {LCD|CRT|TV} [d=iCrtTv] [COMP | SVIDEO] [FLICKER=ON | OFF]
Initializes the S1D13506 registers for a given display type.
Where:
  ? Displays a help message.
  LCD Initializes the LCD registers.
  CRT Initializes the CRT registers.
  TV Initializes the TV registers.
  d = iCrtTv Initializes the CRT/TV for a display configuration based on the following table.

<table>
<thead>
<tr>
<th>iCrtTv</th>
<th>Resolution</th>
<th>Display Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>640x480</td>
<td>CRT</td>
</tr>
<tr>
<td>1</td>
<td>800x600</td>
<td>CRT</td>
</tr>
<tr>
<td>2</td>
<td>752x484</td>
<td>TV (NTSC)</td>
</tr>
<tr>
<td>3</td>
<td>696x436</td>
<td>TV (NTSC)</td>
</tr>
<tr>
<td>4</td>
<td>640x480</td>
<td>TV (NTSC)</td>
</tr>
<tr>
<td>5</td>
<td>920x572</td>
<td>TV (PAL)</td>
</tr>
<tr>
<td>6</td>
<td>856x518</td>
<td>TV (PAL)</td>
</tr>
<tr>
<td>7</td>
<td>800x572</td>
<td>TV (PAL)</td>
</tr>
<tr>
<td>8</td>
<td>640x480</td>
<td>TV (PAL)</td>
</tr>
</tbody>
</table>

COMP Initializes for Composite video output (TV only).
SVIDEO Initializes for SV video output (TV only).
FLICKER=ON Initializes for Flicker Filter enabled (TV only).
FLICKER=OFF Initializes for Flicker Filter disabled (TV only).
**IC {LCD|CRT|TV}**
Initializes the Hardware Cursor for a given display type.
Where:
- **LCD** Initializes for the LCD display.
- **CRT** Initializes for the CRT display.
- **TV** Initializes for the TV display.

**II {LCD|CRT|TV}**
Initializes the Ink Layer for a given display type.
Where:
- **LCD** Initializes for the LCD display.
- **CRT** Initializes for the CRT display.
- **TV** Initializes for the TV display.

**L {LCD|CRT|TV} index [red green blue]**
Writes red, green, and blue Look-Up Table (LUT) components for a given display type. If the red, green, and blue components are not specified, reads the components at the given index.
Where:
- **LCD** LUT used by the LCD display.
- **CRT** LUT used by the CRT display.
- **TV** LUT used by the TV display.
- **index** Index into the LUT (hex).
- **red** Red component of the LUT (hex).
- **green** Green component of the LUT (hex).
- **blue** Blue component of the LUT (hex).

**Note**
Only bits 7-4 of each color are used in the LUT. For example, 10h is the first color intensity after 00h. Valid LUT colors follow the pattern 00h, 10h, 20h, 30h,...E0h, F0h.

**LA {LCD|CRT|TV}**
Reads all LUT values for a given display.
Where:
- **LCD** Reads LUT values for LCD display.
- **CRT** Reads LUT values for CRT display.
- **TV** Reads LUT values for TV display.

**Note**
Only bits 7-4 of each color are used in the LUT. For example, 10h is the first color intensity after 00h. Valid LUT colors follow the pattern 00h, 10h, 20h, 30h,...E0h, F0h.
M [?] {LCD|CRT|TV} [bpp]
Sets the color depth (bpp) for the specified display type. If no color depth is provided, information about the current setting on the specified display are listed.
Where:

? Displays basic information on the current mode for a given display.

LCD Sets the color depth of the LCD display.

CRT Sets the color depth of the CRT display.

TV Sets the color depth of the TV display.

bpp Color depth to be set (4/8/16 bpp).

MC [?] {LCD|CRT|TV} [bpp]
Gets extended information and sets the color depth (bpp).
Where:

? Displays further information on the current mode for a given display.

LCD Sets the color depth of the LCD display.

CRT Sets the color depth of the CRT display.

TV Sets the color depth of the TV display.

bpp Color depth to be set (4/8/16 bpp).

Q
Quits the program.

R addr [count]
Reads a certain number of bytes from the specified address. If no value is provided for count, it defaults to 10h.
Where:

addr Address from which byte(s) will be read (hex).

count Number of bytes to be read (hex).

RD addr [count]
Reads a certain number of dwords from the specified address. If no value is provided for count, it defaults to 10h.
Where:

addr Address from which dword(s) will be read (hex).

count Number of dwords to be read (hex).

RW addr [count]
Reads a certain number of words from the specified address. If no value is provided for count, it defaults to 10h.
Where:

addr Address from which word(s) will be read (hex).

count Number of words to be read (hex).
**S {CLKI | CLKI2 | BUSCLK} freq**
Sets PCLK source frequency (in kHz).
Where:
- CLKI: Sets PCLK source to CLKI.
- CLKI2: Sets PCLK source to CLKI2.
- BUSCLK: Sets PCLK source to BUSCLK.
- freq: Sets the frequency of the PCLK source (decimal value).

**V**
Calculates the current frame rate for all enabled display devices. The frame rate is calculated from the VNDP count.

**W addr data ...**
Writes byte(s) of data to specified memory address.
Where:
- addr: Address data is written to
- data: Data to be written (hex). Data can be a list of bytes that will be repeated for the duration of the write. To use decimal values, attach a “t” suffix to the value. (e.g. 100t is 100 decimal).

**WD addr data ...**
Writes dword(s) of data to specified memory address.
Where:
- addr: Address data is written to
- data: Data to be written (hex). Data can be a list of dwords that will be repeated for the duration of the write. To use decimal values, attach a “t” suffix to the value. (e.g. 100t is 100 decimal).

**WW addr data ...**
Writes word(s) of data to specified memory address.
Where:
- addr: Address data is written to
- data: Data to be written (hex). Data can be a list of words that will be repeated for the duration of the write. To use decimal values, attach a “t” suffix to the value. (e.g. 100t is 100 decimal).

**X index [data]**
Writes byte data to the register at index. If no data is specified, reads the 8-bit (byte) data from the register at index.
Where:
- index: Index into the registers (hex).
- data: Data to be written to/read from register (hex). Data can be a list of bytes that will be repeated for the duration of the write. To use decimal values, attach a “t” suffix to the value. (e.g. 100t is 100 decimal).
**XA**
Reads all the S1D13506 registers.

**XD index [data]**
Writes dword data to the register at index. If no data is specified, reads the 32-bit (dword) data from the register at index.

Where:
- **index** Index into the registers (hex).
- **data** Data to be written to/read from register (hex). Data can be a list of dwords that will be repeated for the duration of the write. To use decimal values, attach a “t” suffix to the value. (e.g. 100t is 100 decimal).

**XW index [data]**
Writes word data to the register at index. If no data is specified, reads the 16-bit (word) data from the register at index.

Where:
- **index** Index into the registers (hex).
- **data** Data to be written to/read from register (hex). Data can be a list of words that will be repeated for the duration of the write. To use decimal values, attach a “t” suffix to the value. (e.g. 100t is 100 decimal).

? Displays the help screen.
13506PLAY Example

1. Type `13506PLAY` to start the program.
2. Type `?` for help.
3. Type `i LCD` to initialize the registers.
4. Type `xa` to display the contents of the registers.
5. Type `x 34` to read register 34h.
6. Type `x 34 10` to write 10h to register 34h.
7. Type `f 0 ffff aa` to fill the first FFFFh bytes of the display buffer with AAh.
8. Type `f 0 1fffff aa` to fill 2M bytes of the display buffer with AAh.
9. Type `r 0 100` to read the first 100h bytes of the display buffer.
10. Type `q` to exit the program.
Scripting

13506PLAY can be driven by a script file. This is useful when:

- there is no display output and a current register status is required.
- various registers must be quickly changed to view results.

A script file is an ASCII text file with one 13506PLAY command per line. All scripts must end with a “q” (quit) command.

On a PC platform, a typical script command line might be:
“13506PLAY < dumpregs.scr > results.”

This causes the file “dumpregs.scr” to be interpreted as commands by 13506PLAY and the results to be sent to the file “results.”

Example: Create an ASCII text file that contains the commands i, xa, and q.

; This file initializes the S1D13506 and reads the registers.
; Note: after a semicolon (;), all characters on a line are ignored.
; Note: all script files must end with the “q” command.

i
xa
q

Comments

- All displayed numeric values are considered to be hexadecimal unless identified otherwise. For example, 10 = 10h = 16 decimal; 10t = 10 decimal; 010b = 2 decimal.
- Redirecting commands from a script file (PC platform) allows those commands to be executed as though they were typed.
Program Messages

**ERROR: Could not map memory from evaluation board to host platform.**
This message should only be shown for DOS platforms. In this case the DOS extender could not be initialized, or was unable to get the linear address of the display memory.

**ERROR: Not enough display buffer memory.**
There was insufficient display buffer memory for the given configuration. Memory requirements depend on:

- the display resolution(s).
- the bit-per-pixel depth(s).
- whether a half-frame buffer is required.
- the number of displays active (LCD or LCD and CRT/TV).

**ERROR: Not enough memory for LCD/CRT/TV in 4/8/16 bits-per-pixel.**
13506BMP is unable to change the color depth due to insufficient display buffer memory. Memory requirements depend on:

- the display resolution(s).
- the bit-per-pixel depth(s).
- whether a half-frame buffer is required.
- the number of displays active (LCD or LCD and CRT/TV).

**ERROR: PCI bridge adapter not found.**
The Windows PCI driver did not find the PCI Bridge Adapter.

**ERROR: PCI driver not found.**
The Windows PCI driver is not loaded.

**ERROR: Program not configured for LCD/CRT/TV. Run 13506CFG and configure for LCD/CRT/TV.**
The program was configured by 13506CFG for a display device that is not available. This typically occurs if the wrong command line was entered for the current configuration.

**WARNING: CLKI frequency not in HAL table. Program assumes that external oscillator is used.**
**WARNING: CLKI2 frequency not in HAL table. Program assumes that external oscillator is used.**
The correct frequency was not found in the HAL table used to program the clock synthesizer. An external oscillator may be in use. This warning message will not stop the program.

**ERROR: At least one of the displays must be enabled.**
This message is shown when 13506PLAY received the V command, but no display is enabled. At least one display must be enabled for the V command to function (5 seconds of VNDP pulses are counted to calculate the frame rate).

**ERROR: Invalid iFreq value.**
The CLKI and/or CLKI2 commands were used with an invalid iFreq value. To display a list of iFreq values, type "CLKI ?" or "CLKI2 ?".
ERROR: Not enough display buffer memory for LCD/CRT/TV cursor/ink layer.
There was insufficient display buffer memory for the given Hardware Cursor/Ink Layer configuration. Memory requirements depend on:

- the display resolution(s).
- the bit-per-pixel depth(s).
- whether a half-frame buffer is required.
- the number of displays active (LCD or LCD and CRT/TV).

WARNING: FEATCLK cannot be multiplexed to CLKI. Clock synthesizer programmed instead.
In 13506PLAY, the CLKI command was used to select the FEATCLK frequency. Since the FEATCLK can only be multiplexed to CLKI2, the clock synthesizer is programmed instead.
S1D13506 Color LCD/CRT/TV Controller

13506BMP Demonstration Program

Document Number: X25B-B-004-02
13506BMP

13506BMP is a demonstration utility used to show the S1D13506 display capabilities by rendering bitmap images on the display device(s). The program will display any bitmap stored in Windows BMP file format and then exit. 13506BMP supports SviwelView™ (90°, 180°, and 270° hardware rotation of the display image).

13506BMP is designed to operate on a personal computer (PC) within a 32-bit environment only (Windows ‘95/’98/NT). Other embedded platforms are not supported due to the possible lack of system memory or structured file system.

The 13506BMP demonstration utility must be configured and/or compiled to work with your hardware configuration. The program 13506CFG.EXE can be used to configure 13506BMP. Consult the 13506CFG users guide, document number X25B-B-001-xx, for more information on configuring S1D13506 utilities.

S1D13506 Supported Evaluation Platforms

13506BMP supports the following S1D13506 evaluation platforms:

• PC with an Intel 80x86 processor running Windows ‘95/’98/NT.

Note
The 13506BMP source code may be modified by the OEM to support other evaluation platforms.

Installation

Copy the file 13506bmp.exe to a directory in the path (e.g. PATH=C:\S1D13506).
Usage

At the prompt, type:

```
13506bmp bmpfile [ds=n | ds=?] [/noinit] [/r90 | /r180 | /r270] [/v] [/?]
```

Where:

- **bmpfile**: specifies filename of a windows format bmp image
- **ds=n**: selects display surfaces (see Section “Display Surfaces” on page 5)
- **ds=?**: shows available display surfaces (see Section “Display Surfaces” on page 5)
- **/noinit**: skips full register initialization. Only registers used for changing the color depth (bpp), selecting the memory/registers and programming the clock synthesizer are updated. Additionally, some registers are read to determine information such as display size and type (LCD, CRT, TV).
- **/r90**: SwivelView™ 90°, clockwise hardware rotation of LCD image by 90 degrees
- **/r180**: SwivelView™ 180°, clockwise hardware rotation of LCD image by 180 degrees
- **/r270**: SwivelView™ 270°, clockwise hardware rotation of LCD image by 270 degrees
- **/v**: verbose mode (provides information about the displayed image)
- **/?**: displays the help message

**Note**

13506BMP will automatically finish execution and return to the prompt.
Display Surfaces

A surface is a block of memory assigned to one or more physical display devices. 13506BMP provides 7 display surfaces (0-6) which cover the possible combinations of display types. Table 1, “Display Surfaces” lists the predefined display surfaces that may be selected.

Display surfaces 0 through 2 each display data from a single memory block to an individual display device (LCD, CRT, or TV).

Display surfaces 3 and 4 output to two separate display devices, but generate the output from the same memory block. This may be useful when the same image is to be displayed on both display devices. It also reduces the total amount of display memory required.

Display surfaces 5 and 6 output to two separate devices from different memory blocks. This allows two completely different images to be displayed at the same time. When using display surfaces 5 or 6, some combinations of display modes with a high resolution and/or high color depth may not be supported within a 2MB display buffer.

<table>

Display surfaces 0 through 2 each display data from a single memory block to an individual display device (LCD, CRT, or TV).
13506BMP Examples

To display a bmp image on an LCD, type the following:
13506bmp bmpfile.bmp ds=0

To display a bmp image on a CRT, type the following:
13506bmp bmpfile.bmp ds=1

To display a bmp image on an LCD with 90° SwivelView™ enabled, type the following:
13506bmp bmpfile.bmp ds=0 /r90

To display a bmp image on both the LCD and CRT, type the following:
13506bmp bmpfile.bmp ds=3

To display independent bmp images on the LCD and TV, type the following:
13506bmp bmpfile.bmp ds=6

Comments

- 13506BMP displays only Windows BMP format images.
- A 24-bit true color bitmap will be displayed at a color depth of 16 bit-per-pixel.
- Only the green component of the image will be seen on a monochrome display.
Program Messages

ERROR: Could not detect S1D13506.
The ID register did not indicate the presence of the S1D13506.

ERROR: Could not map memory from evaluation board to host platform.
This message should only be shown for DOS platforms. In this case the DOS extender could not be initialized, or was unable to get the linear address of the display memory.

ERROR: Failed to open BMP file: 'filename'
Could not open the BMP file.

ERROR: 'filename' is not a valid bitmap file.
The filename given on the command line is not a valid BMP file.

ERROR: In the given display surface configuration, the user must select the same BPP for both LCD and CRT/TV.
When two displays are using an image from the same display memory block, both displays must be configured for the same color depth (bpp).

ERROR: Invalid display surface number.
The "ds=" command line option included an invalid value. The parameter "ds=?" lists the valid numbers.

ERROR: LCD and CRT resolutions must be identical.
LCD: (width, height)
CRT: (width, height)
When the LCD and CRT are using an image from the same display memory block, both displays must be the same resolution.

ERROR: LCD and TV resolutions must be identical.
LCD: (width, height)
TV: (width, height)
When the LCD and TV are using an image from the same display memory block, both displays must be the same resolution.

ERROR: LCD must be in landscape mode.
The LCD panel must be configured for landscape mode if both the LCD display and CRT/TV are active.

ERROR: Not enough display buffer memory.
There was insufficient display buffer memory for the given configuration. Memory requirements depend on:

- the display resolution(s).
- the bit-per-pixel depth(s).
- whether a half-frame buffer is required.
- the number of displays active (LCD or LCD and CRT/TV).
ERROR: Not enough memory for LCD/CRT/TV in 4/8/15/16 bits-per-pixel.
13506BMP is unable to change the color depth due to insufficient display buffer memory. Memory requirements depend on:

- the display resolution(s).
- the bit-per-pixel depth(s).
- whether a half-frame buffer is required.
- the number of displays active (LCD or LCD and CRT/TV).

ERROR: Not enough memory for virtual display.
A virtual display is required for SwivelView™. This error message indicates there is insufficient memory for the given configuration. Memory requirements depend on:

- the display resolution(s).
- the bit-per-pixel depth(s).
- whether a half-frame buffer is required.
- the number of displays active (LCD or LCD and CRT/TV).

ERROR: PCI bridge adapter not found.
The Windows PCI driver did not find the PCI Bridge Adapter.

ERROR: PCI driver not found.
The Windows PCI driver is not loaded.

ERROR: Program not configured for LCD/CRT/TV. Run 13506CFG and configure for LCD/CRT/TV.
The program was configured by 13506CFG for a display device that is not available. This typically occurs if the wrong command line was entered for the current configuration.

WARNING: CLKI frequency not in HAL table. Program assumes that external oscillator is used.
WARNING: CLKI2 frequency not in HAL table. Program assumes that external oscillator is used.
The correct frequency was not found in the HAL table used to program the clock synthesizer. An external oscillator may be in use. This warning message will not stop the program.

WARNING: CRT/TV only available in LANDSCAPE mode.
SwivelView™ is only available on LCD only configurations.
THIS PAGE LEFT BLANK
13506FILT

13506FILT is an interactive Windows® 9x/NT program that enables/disables the S1D13506 TV Filters. It demonstrates the effect each filter has on a pre-loaded TV image. 13506FILT is particularly useful in a test or demonstration environment where 13506FILT is run on one display and the effects of enabling/disabling each filter are seen on a TV. An OEM may find this useful in determining the appropriate filters for their application.

Note
The 13506FILT dialog box doesn’t appear on any display device controlled by the S1D13506. The 13506FILT dialog box appears on the Win 9x/NT desktop.

13506FILT is designed to operate on a personal computer (PC) within a 32-bit environment only (Windows 9x/NT). Other embedded platforms are not supported.

S1D13506 Supported Evaluation Platforms

13506FILT supports the following S1D13506 evaluation platforms:
• PC with an Intel 80x86 processor running Windows 9x/NT.

Installation

Copy the file 13506filt.exe to a directory in the path. If desired, create a shortcut on the Windows 9x/NT desktop to the file 13506filt.exe.

Usage

In Windows ‘9x/NT, double-click the following icon:

Or, at the Windows DOS Prompt, type 13506filt.
Filter Dialog Box

The filter dialog box controls which TV filters are enabled/disabled during NTSC or PAL output. The check box for each filter determines if the filter is enabled or disabled. When the box is checked the filter is enabled. When the box is unchecked the filter is disabled. In the example below:

- the flicker filter is disabled.
- the chrominance filter is enabled.
- the luminance filter is enabled.

Figure 1: Filter Dialog Box
Filter Descriptions

When displaying computer images on a TV, several image distortions are likely to arise:

- flickering.
- cross-chrominance distortion.
- cross-luminance distortion.

These distortions are caused by the high-resolution nature of computer images which typically contain sharp chrominance (color) transitions, and sharp luminance (brightness) transitions. Three filters are available to reduce these distortions.

Anti-flicker Filter

The “flickering” effect seen on interlaced displays is caused by sharp vertical image transitions that occur over one line (1 vertical pixel). For example, flickering may occur where there are one pixel high lines, edges of window boxes, etc. Flickering occurs because these high resolution lines are effectively displayed at half the refresh frequency due to interlacing. To reduce flickering, the anti-flicker filter averages adjacent lines on the TV display.

Chrominance Filter

The chrominance filter adjusts the color of the TV by limiting the bandwidth of the chrominance signal (reducing cross-luminance distortion). This reduces the “ragged edges” seen at boundaries between sharp color transitions. This filter is intended for use with composite video output.

Luminance Filter

The luminance filter adjusts the brightness of the TV by limiting the bandwidth of the luminance signal (reducing cross-chrominance distortion). This reduces the “rainbow-like” colors at boundaries between sharp luminance transitions. This filter is intended for use with composite video output.

Comments

- The Flicker Filter can’t be enabled unless a TV is present and active.
- 13506FILT is designed to show the effects of the filters on a pre-loaded TV image. 13506BMP may be used to display a static image on the TV (see the 13506BMP Users Manual, document number X25B-B-004-xx).
- The chrominance and luminance filters are intended for use with composite output.
- For information on manually enabling/disabling the TV filters, refer to the SID13506 Hardware Functional Specification (document number X25B-A-001-xx) and the SID13506 Programming Notes and Examples (document number X25B-G-003-xx).
13506SWIVEL

13506SWIVEL is a command line utility that demonstrates the SwivelView™ feature of the S1D13506. The SwivelView feature provides hardware rotation of a predefined image by 90°, 180°, and 270° in a clockwise direction. 13506SWIVEL cycles through each SwivelView mode, advancing to the next mode when a key is pressed.

13506SWIVEL is designed to operate on a personal computer (PC) within a 32-bit environment only (Windows 9x/NT). Other embedded platforms are not supported.

The 13506SWIVEL utility must be configured and/or compiled to work with your hardware configuration. The program 13506CFG.EXE can be used to configure 13506SWIVEL. Consult the 13506CFG Users Manual, document number X25B-B-001-xx, for more information on configuring S1D13506 utilities.

S1D13506 Supported Evaluation Platforms

13506SWIVEL supports the following S1D13506 evaluation platforms:

- PC with an Intel 80x86 processor running Windows 9x/NT.

Installation

Copy the file 13506swivel.exe to a directory in the path. If desired, create a shortcut on the Windows 9x/NT desktop to the file 13506swivel.exe.

Usage

At the Windows DOS Prompt, type:

13506swivel

Note

Pressing the ESC key exits the program.
Example

1. Run the utility 13506SWIVEL. At the Windows DOS prompt type:

   13506swivel

   **Note**
   A pattern of colored numbers appears in SwivelView 0° mode (normal landscape).

2. Press any key to enable SwivelView 90° mode. The displayed image is rotated by 90°.

3. Press any key to enable SwivelView 180° mode. The displayed image is rotated by 180°.

4. Press any key to enable SwivelView 270° mode. The displayed image is rotated by 270°.

5. Press any key to return to SwivelView 0° mode (normal landscape).

6. Press the ESC key to exit the program.

   **Note**
   13506SWIVEL will continue to cycle through the SwivelView modes in the above order until the ESC key is pressed.

Comments

- 13506SWIVEL supports LCD panels only (no CRT or TV).
- 13506SWIVEL only supports 8/15/16 bpp color depths.
- 13506SWIVEL must be configured for LCD only using the utility 13506CFG. For further information on 13506CFG, refer to the *13506CFG Users Manual*, document number X25B-B-001-xx.
- For further information on SwivelView™, refer to the *S1D13506 Hardware Functional Specification* (document number X25B-A-001-xx) and the *S1D13506 Programming Notes and Examples* (document number X25B-G-003-xx).
S1D13506 Color LCD/CRT/TV Controller

Windows® CE 2.x Display Drivers

Document Number: X25B-E-001-06
The Windows CE display driver is designed to support the S1D13506 Color LCD/CRT/TV Controller running under the Microsoft Windows CE 2.x operating system. The driver is capable of: 4, 8 and 16 bit-per-pixel landscape modes (no rotation), and 4, 8 and 16 bit-per-pixel SwivelView™ 90 degree, 180 degree and 270 degree modes.

This document and the source code for the Windows CE drivers are updated as appropriate. Before beginning any development, please check the Epson Electronics America Website at www.eea.epson.com or the Epson Research and Development Website at www.erd.epson.com for the latest revisions.

We appreciate your comments on our documentation. Please contact us via email at techpubs@erd.epson.com.
Example Driver Builds

The following sections describe how to build the Windows CE display driver for:

1. Windows CE 2.0 using a command-line interface.
2. Windows CE Platform Builder 2.1x using a command-line interface.

In all examples “x:” refers to the drive letter where Platform Builder is installed.

Build for CEPC (X86) on Windows CE 2.0 using a Command-Line Interface

To build a Windows CE v2.0 display driver for the CEPC (X86) platform using a S5U13506B00C evaluation board, follow the instructions below:

1. Install Microsoft Windows NT v4.0 or 2000.
2. Install Microsoft Visual C/C++ version 5.0 or 6.0.
3. Install the Microsoft Windows CE Embedded Toolkit (ETK) by running SETUP.EXE from the ETK compact disc #1.
4. Create a new project by following the procedure documented in “Creating a New Project Directory” from the Windows CE ETK v2.0. Alternately, use the current “DEMO7” project included with the ETK v2.0. Follow the steps below to create a “X86 DEMO7” shortcut on the Windows NT v4.0 desktop which uses the current “DEMO7” project:
   a. Right click on the “Start” menu on the taskbar.
   b. Click on the item “Open All Users” and the “Start Menu” window will come up.
   c. Click on the icon “Programs”.
   d. Click on the icon “Windows CE Embedded Development Kit”.
   e. Drag the icon “X86 DEMO1” onto the desktop using the right mouse button.
   f. Click on “Copy Here”.
   g. Rename the icon “X86 DEMO1” on the desktop to “X86 DEMO7” by right clicking on the icon and choosing “rename”.
   h. Right click on the icon “X86 DEMO7” and click on “Properties” to bring up the “X86 DEMO7 Properties” window.
   i. Click on “Shortcut” and replace the string “DEMO1” under the entry “Target” with “DEMO7”.
   j. Click on “OK” to finish.
5. Create a sub-directory named S1D13506 under x:\wince\platform\cepc\drivers\display.
6. Copy the source code to the S1D13506 subdirectory.
7. Edit the file x:\wince\platform\cepc\drivers\display\dirs and add S1D13506 into the list of directories.

8. Edit the file PLATFORM.BIB (located in x:\wince\platform\cepc\files) to set the default display driver to the file EPSON.DLL (EPSON.DLL will be created during the build in step 13).

Replace or comment out the following lines in PLATFORM.BIB:

```
IF CEPC_DDI_VGA2BPP
    ddi.dll $(FLATRELEASEDIR)\ddi_vga2.dll NK SH
ENDIF
```
```
IF CEPC_DDI_VGA8BPP
    ddi.dll $(FLATRELEASEDIR)\ddi_vga8.dll NK SH
ENDIF
```
```
IF CEPC_DDI_VGA2BPP !
    IF CEPC_DDI_VGA8BPP !
        ddi.dll $(FLATRELEASEDIR)\ddi_s364.dll NK SH
    ENDIF
ENDIF
```
```
with this line:
```
    ddi.dll $(FLATRELEASEDIR)\EPSON.dll NK SH
```
```
```

9. The file MODE0.H (located in x:\wince\platform\cepc\drivers\display\S1D13506) contains the register values required to set the screen resolution, color depth (bpp), display type, active display (LCD/CRT/TV), display rotation, etc.

Before building the display driver, refer to the descriptions in the file MODE0.H for the default settings of the driver. If the default does not match the configuration you are building for then MODE0.H will have to be regenerated with the correct information.

Use the program 13506CFG to generate the header file. For information on how to use 13506CFG, refer to the 13506CFG Configuration Program User Manual, document number X25B-B-001-xx, available at www.erd.epson.com

After selecting the desired configuration, export the file as a “C Header File for S1D13506 WinCE Drivers”. Save the new configuration as MODE0.H in x:\wince\platform\cepc\drivers\display\S1D13506, replacing the original configuration file.

10. Edit the file PLATFORM.REG to match the screen resolution, color depth (bpp), active display (LCD/CRT/TV) and rotation information in MODE.H. PLATFORM.REG is located in x:\wince\platform\cepc\files.
For example, the display driver section of PLATFORM.REG should be as follows when using a 640x480 LCD panel with a color depth of 8 bpp in SwivelView 0° (landscape) mode:

; Default for EPSON Display Driver
; 640x480 at 8 bits/pixel, LCD display, no rotation
; Useful Hex Values
; 1024=0x400, 768=0x300 640=0x280 480=0x1E0 320=0x140 240=0xF0
[HKEY_LOCAL_MACHINE\Drivers\Display\S1D13506]
"Width"=dword:280
"Height"=dword:1E0
"Bpp"=dword:8
"ActiveDisp"=dword:1
"Rotation"=dword:0

11. Delete all the files in the x:\wince\release directory, and delete x:\wince\platform\cepc\*.bif

12. Generate the proper building environment by double-clicking on the sample project icon (i.e. X86 DEMO7).

13. Type BLDDEMO <ENTER> at the command prompt of the X86 DEMO7 window to generate a Windows CE image file (NK.BIN).

**Build for CEPC (X86) on Windows CE Platform Builder 2.1x using a Command-Line Interface**

Throughout this section 2.1x refers to either 2.11 or 2.12 as appropriate.

1. Install Microsoft Windows NT v4.0 or 2000.

2. Install Microsoft Visual C/C++ version 5.0 or 6.0.

3. Install Platform Builder 2.1x by running SETUP.EXE from compact disk #1.

4. Follow the steps below to create a “Build Epson for x86” shortcut which uses the current “Minshell” project icon/shortcut on the Windows desktop.
   a. Right click on the “Start” menu on the taskbar.
   b. Click on the item “Explore”, and “Exploring -- Start Menu” window will come up.
   c. Under “x:\winnt\profiles\all users\start menu\programs\microsoft windows ce platform builder\x86 tools”, find the icon “Build Minshell for x86”.
   d. Drag the icon “Build Minshell for x86” onto the desktop using the right mouse button.
e. Choose “Copy Here”.

f. Rename the icon “Build Minshell for x86” to “Build Epson for x86” by right clicking on the icon and choosing “rename”.

g. Right click on the icon “Build Epson for x86” and click on “Properties” to bring up the “Build Epson for x86 Properties” window.

h. Click on “Shortcut” and replace the string “Minshell” under the entry “Target” with “Epson”.

i. Click on “OK” to finish.

5. Create an EPSON project.

a. Make an Epson directory under x:\wince\public.

b. Copy MAXALL and its sub-directories (x:\wince\public\maxall) to the Epson directory.

xcopy /s /e x:\wince\public\maxall\*.* x:\wince\public\epson

c. Rename x:\wince\public\epson\maxall.bat to epson.bat.

d. Edit EPSON.BAT to add the following lines to the end of the file:

@echo on
set CEPC_DDI_S1D13506=1
@echo off

6. Make an S1D13506 directory under x:\wince\platform\cepc\drivers\display, and copy the S1D13506 driver source code into x:\wince\platform\cepc\drivers\display\S1D13506.

7. Edit the file x:\wince\platform\cepc\drivers\display\dirs and add S1D13506 into the list of directories.

8. Edit the file x:\wince\platform\cepc\files\platform.bib and make the following two changes:

a. Insert the following text after the line “IF ODO_NODISPLAY !”:

IF CEPC_DDI_S1D13506
    ddi.dll $(\_FLATRELEASEDIR)\epson.dll NK SH
ENDIF

b. Find the section shown below, and insert the lines as marked:

IF CEPC_DDI_S1D13506 ! Insert this line
IF CEPC_DDI_S3VIRGE !
IF CEPC_DDI_CT655X !
IF CEPC_DDI_VGA8BPP !
The file MODE0.H (located in x:\wince\platform\cepc\drivers\display\S1D13506) contains the register values required to set the screen resolution, color depth (bpp), display type, active display (LCD/CRT/TV), display rotation, etc.

Before building the display driver, refer to the descriptions in the file MODE0.H for the default settings of the driver. If the default does not match the configuration you are building for then MODE0.H will have to be regenerated with the correct information.

Use the program 13506CFG to generate the header file. For information on how to use 13506CFG, refer to the 13506CFG Configuration Program User Manual, document number X25B-B-001-xx, available at www.erd.epson.com

After selecting the desired configuration, export the file as a “C Header File for S1D13506 WinCE Drivers”. Save the new configuration as MODE0.H in x:\wince\platform\cepc\drivers\display\S1D13506, replacing the original configuration file.

Edit the file PLATFORM.REG to match the screen resolution, color depth (bpp), active display (LCD/CRT/TV) and rotation information in MODE.H. PLATFORM.REG is located in x:\wince\platform\cepc\files.

For example, the display driver section of PLATFORM.REG should be as follows when using a 640x480 LCD panel with a color depth of 8 bpp in SwivelView 0° (landscape) mode:

; Default for EPSON Display Driver
; 640x480 at 8 bits/pixel, LCD display, no rotation
; Useful Hex Values
; 1024=0x400, 768=0x300 640=0x280 480=0x1E0 320=140 240=0xF0

[HKEY_LOCAL_MACHINE\Drivers\Display\S1D13506]
"Width"=dword:280
"Height"=dword:1E0
"Bpp"=dword:8
"ActiveDisp"=dword:1
"Rotation"=dword:0

11. Delete all the files in \wince\release directory and delete x:\wince\platform\cepc\*.bif
12. Generate the proper building environment by double-clicking on the Epson project icon --“Build Epson for x86”.

13. Type BLDDEMO <ENTER> at the command prompt of the “Build Epson for x86” window to generate a Windows CE image file (NK.BIN).
Installation for CEPC Environment

Once the NK.BIN file is built, the CEPC environment can be started by booting either from a floppy or hard drive configured with a Windows 9x operating system. The two methods are described below.

1. To start CEPC after booting from a floppy drive:
   a. Create a bootable floppy disk.
   b. Edit CONFIG.SYS on the floppy disk to contain only the following line:
      
      ```
      device=a:\himem.sys
      ```
   c. Edit AUTOEXEC.BAT on the floppy disk to contain the following lines:
      
      ```
      mode com1:9600,n,8,1
      loadcepc /B:9600 /C:1 c:\nk.bin
      ```
   d. Copy LOADCEPC.EXE and HIMEM.SYS to the bootable floppy disk. Search for the loadCEPC utility in your Windows CE directories.
   e. Copy NK.BIN to c:\
   f. Boot the system from the bootable floppy disk.

2. To start CEPC after booting from a hard drive:
   a. Copy LOADCEPC.EXE to C:\. Search for the loadCEPC utility in your Windows CE directories.
   b. Edit CONFIG.SYS on the hard drive to contain only the following line:
      
      ```
      device=c:\himem.sys
      ```
   c. Edit AUTOEXEC.BAT on the hard drive to contain the following lines:
      
      ```
      mode com1:9600,n,8,1
      loadcepc /B:9600 /C:1 c:\nk.bin
      ```
   d. Copy NK.BIN and HIMEM.SYS to c:\
   e. Boot the system.
Configuration

There are several issues to consider when configuring the display driver. The issues cover debugging support, register initialization values and memory allocation. Each of these issues is discussed in the following sections.

Compile Switches

There are several switches, specific to the S1D13506 display driver, which affect the display driver.

The switches are added or removed from the compile options in the file SOURCES.

WINCEVER

This option is automatically set to the numerical version of WinCE for version 2.12 or later. If the environment variable, _WINCEOSVER is not defined, then WINCEVER will default 2.11. The display driver may test against this option to support different WinCE version-specific features.

EnablePreferVmem

This option enables the use of off-screen video memory. When this option is enabled, WinCE can optimize some BLT operations by using off-screen video memory to store images. You may want to disable this option if you have limited off-screen display memory.

Enable2DC

This option enables the S1D13506 display driver to support an alternate device context. This may be useful for applications such as Pocket PowerPoint, which can display a different image on a display device other than the primary display. The driver support for this is still under development and is untested.

Future releases of the S1D13506 display drivers will have full support for alternate displays.

EnableDC2Hwblt

This option enables hardware BLT acceleration on the alternate display (see Enable2DC). This option is currently unused and will be fully supported in future releases of the S1D13506 display drivers.
ENABLE_CLOCK_CHIP

This option is used to enable support for the ICD2061A clock generator. This clock chip is used on the S5U13506B00C evaluation board. The S1D13506 display drivers can program the clock chip to support the frequencies required in the MODE tables.

If you are not using the S5U13506B00C evaluation adapter, you should disable this option.

ENABLE_ANTIALIASED_FONTS

This option enables the display driver support of antialiased fonts in WinCE. Fonts created with the ANTIALIASED_QUALITY attribute will be drawn with font smoothing.

If you want all fonts to be antialiased by default, add the following line to PLATFORM.REG: [HKEY_LOCAL_MACHINE\SYSTEM\GDI\Fontsmoothing]. This registry option causes WinCE to draw all fonts with smoothing.

This option is only applicable to 16bpp mode.

EpsonMessages

This debugging option enables the display of EPSON-specific debug messages. These debug message are sent to the serial debugging port. This option should be disabled unless you are debugging the display driver, as they will significantly impact the performance of the display driver.

DEBUG_MONITOR

This option enables the use of the debug monitor. The debug monitor can be invoked when the display driver is first loaded and can be used to view registers, and perform a few debugging tasks. The debug monitor is still under development and is untested.

This option should remain disabled unless you are performing specific debugging tasks that require the debug monitor.

MonoPanel

This option is intended for the support of monochrome panels only.

The option causes palette colors to be grayscaled for correct display on a mono panel. For use with color panels this option should not be enabled.

TEST_BITMAP

This option allows the debug monitor to display a test bitmap. This bitmap is big and will make the display driver considerably larger. The flag DEBUG_MONITOR must also be enabled for this option to work.
This option should be disabled unless the image is required for debugging.

**DEBUG_BLT**

This option enables special BLT debugging messages on the debugging serial port. This option, when enabled, will drastically impact display driver performance, and should only be used to track down failures in the BLT operations.

This option should be disabled unless doing BLT debugging.

**FILL_DELETED_OFFSCREEN_SURFACE**

This option enables special debugging code that will fill (blank) off-screen rectangular surfaces when they are destructed. This option is only useful if EnablePreferVmem is also enabled. When enabled, off-screen surfaces are filled with a solid color when they are deleted. If any code then attempts to reuse the deleted off screen surface, the results should show up as errors on the primary display.

This option should be disabled unless doing debugging.

**Mode File**

A second variable which will affect the finished display driver is the register configurations contained in the mode file.

The MODE tables (contained in files MODE0.H, MODE1.H, MODE2.H . . . ) contain register information to control the desired display mode. The MODE tables must be generated by the configuration program 13506CFG.EXE. The display driver comes with example MODE tables.

By default, only MODE0.H is used by the display driver. New mode tables can be created using the 13506CFG program. Edit the #include section of MODE.H to add the new mode table.

If you only support a single display mode, you do not need to add any information to the WinCE registry. If, however, you support more that one display mode, you should create registry values (see below) that will establish the initial display mode. If your display driver contains multiple mode tables, and if you do not add any registry values, the display driver will default to the **first** mode table in your list.

To select which display mode the display driver should use upon boot, add the following lines to your PLATFORM.REG file:

```
[HKEY_LOCAL_MACHINE\Drivers\Display\S1D13506]

"Width"=dword:280
"Height"=dword:1E0
"Bpp"=dword:8
```
“Rotation”=dword:0
“RefreshRate”=dword:3C
“Flags”=dword:2

Note that all dword values are in hexadecimal, therefore 280h = 640, 1E0h = 480, and 3Ch = 60. The value for “Flags” should be 1 (LCD), 2 (CRT), or 3 (both LCD and CRT). When the display driver starts, it will read these values in the registry and attempt to match a mode table against them. All values must be present and valid for a match to occur, otherwise the display driver will default to the FIRST mode table in your list.

A WinCE desktop application (or control panel applet) can change these registry values, and the display driver will select a different mode upon warmboot. This allows the display driver to support different display configurations and/or orientations. An example application that controls these registry values will be made available upon the next release of the display driver; preliminary alpha code is available by special request.

Comments

- The display driver is CPU independent, allowing use of the driver for several Windows CE Platform Builder supported platforms.
- By default, the 13506CFG program assumes PCI addressing for the S5U13506B00C evaluation board. This means that the display driver will automatically locate the S1D13506 by scanning the PCI bus (currently only supported for the CEPC platform). If you select the address option “Other” and fill in your own custom addresses for the registers and video memory, then the display driver will not scan the PCI bus and will use the specific addresses you have chosen.
- When using the display driver on hardware other than the S5U13506B00C evaluation board, you must ensure that your hardware provides the correct clock frequencies for CLKI, CLKI2, and CLKI3. The 13506CFG program defaults CLKI to 25.175MHz, CLKI2 to 14.318MHz, and CLKI3 to 50.000MHz. The 13506CFG program also defaults BUSCLK to the PCI clock of 33.333MHz.

On the evaluation board, the display driver will correctly program the clock chip to support the CLKI and CLKI2 frequencies, and BUSCLK is derived from the PCI clock. On customer hardware, you must ensure that the clocks you provide to all clock inputs match the settings you chose in the Clocks tab of the 13506CFG program.

If you run the S1D13506 with a single clock source, make sure your clock sources for LCD, CRT, MediaPlug, and MCLK are correctly set to use the correct clock input source (typically BUSCLK). Also ensure that you enable the clock dividers as required for different display hardware.
• When using 13506CFG.EXE to produce multiple MODE tables, make sure you change the Mode Number in the WinCE tab for each mode table you generate. The display driver supports multiple mode tables, but only if each mode table has a unique mode number.

• The 13506CFG program assumes you are using the S5U13506B00C evaluation board, and defaults the Panel Power control to GPIO11. 13506CFG allows you to change the GPIO pin used to control panel power, or to disable the use of GPIO pins altogether. If this is changed from the default, your driver will no longer be able to enable panel power on the S5U13506B00C evaluation board, and your panel may not be powered up correctly. Using GPIO pins 0, 1, 2, or 12 for panel power control is not recommended as these pins are used by other S5U adapter features (such as clock chip support and the media plug interface).

• At this time, the drivers have been tested on the x86 CPUs and have been run with version 2.0 of the ETK, Platform Builder v2.1x.

S1D13506 Color LCD/CRT/TV Controller

Wind River WindML v2.0 Display Drivers

Document Number: X25B-E-002-03

Copyright © 2001 Epson Research and Development, Inc. All Rights Reserved.

Information in this document is subject to change without notice. You may download and use this document, but only for your own use in evaluating Seiko Epson/EPSON products. You may not modify the document. Epson Research and Development, Inc. disclaims any representation that the contents of this document are accurate or current. The Programs/Technologies described in this document may contain material protected under U.S. and/or International Patent laws.

EPSON is a registered trademark of Seiko Epson Corporation. All other trademarks are the property of their respective owners.
Wind River WindML v2.0 DISPLAY DRIVERS

The Wind River WindML v2.0 display drivers for the S1D13506 Color LCD/CRT/TV Controller are intended as “reference” source code for OEMs developing for Wind River’s WindML v2.0. The driver package provides support for both 8 and 16 bit-per-pixel color depths. The source code is written for portability and contains functionality for most features of the S1D13506. Source code modification is required to provide a smaller, more efficient driver for mass production (e.g. TV support may be removed for products not requiring TV).

The WindML display drivers are designed around a common configuration include file called `mode0.h` which is generated by the configuration utility 13506CFG. This design allows for easy customization of display type, clocks, decode addresses, rotation, etc. by OEMs. For further information on 13506CFG, see the 13506CFG Configuration Program User Manual, document number X25B-B-001-xx.

**Note**

The WindML display drivers are provided as “reference” source code only. They are intended to provide a basis for OEMs to develop their own drivers for WindML v2.0. These drivers are not backwards compatible with UGL v1.2. For information on the UGL v1.2 display drivers, see Wind River UGL v1.2 Display Drivers, document number X25B-E-003-xx.

This document and the source code for the WindML display drivers is updated as appropriate. Please check the Epson Electronics America website at http://www.eea.epson.com or the Epson Research and Development website at http://www.erd.epson.com for the latest revisions before beginning any development.

We appreciate your comments on our documentation. Please contact us via email at documentation@erd.epson.com.
Building a WindML v2.0 Display Driver

The following instructions produce a bootable disk that automatically starts the UGL demo program. These instructions assume that Wind River’s Tornado platform is already installed.

**Note**
For the example steps where the drive letter is given as “x:”. Substitute “x” with the drive letter that your development environment is on.

1. Create a working directory and unzip the WindML display driver into it.
   
   From a command prompt or GUI interface create a new directory (e.g. x:\13506).
   
   Unzip the file **13506windml.zip** to the newly created working directory. The files will be unzipped to the directories “x:\13506\8bpp” and “x:\13506\16bpp”.

2. Configure for the target execution model.
   
   This example build creates a VxWorks image that fits onto and boots from a single floppy diskette. In order for the VxWorks image to fit on the disk certain modifications are required.
   
   Replace the file “x:\Tornado\target\config\pcPentium\config.h” with the file “x:\13506\8bpp\File\config.h” (or “x:\13506\16bpp\File\config.h”). The new **config.h** file removes networking components and configures the build image for booting from a floppy disk.

**Note**
Rather than simply replacing the original **config.h** file, rename it so the file can be kept for reference purposes.

3. Build a boot ROM image.
   
   From the Tornado tool bar, select Build -> Build Boot ROM. Select “pcPentium” as the BSP and “bootrom_uncmp” as the image.

4. Create a bootable disk (in drive A:).
   
   From a command prompt change to the directory “x:\Tornado\host\x86-win32\bin” and run the batch file **torvars.bat**. Next, change to the directory “x:\Tornado\target\config\pcPentium” and type:

   ```
   mkboot a: bootrom_uncmp
   ```

5. If necessary, generate a new **mode0.h** configuration file.
   
   The file **mode0.h** contains the register values required to set the screen resolution, color depth (bpp), display type, active display (LCD/CRT/TV), rotation, etc. The **mode0.h** file included with the drivers, may not contain applicable values and must be regenerated. The configuration program 13506CFG can be used to build a new **mode0.h** file. If building for 8 bpp, place the new **mode0.h** file in the directory “x:\13506\8bpp\File”. If building for 16 bpp, place the new **mode0.h** file in “x:\13506\16bpp\File”.
Note

**Mode0.h** should be created using the configuration utility 13506CFG. For more information on 13506CFG, see the *13506CFG Configuration Program User Manual*, document number X25B-B-001-xx available at www.erd.epson.com.

6. Build the WindML v2.0 library.

From a command prompt change to the directory “x:\Tornado\host\x86-win32\bin” and run the batch file **torvars.bat**. Next, change to the directory “x:\Tornado\target\src\ugl” and type the command:

```
make CPU=PENTIUM ugl
```

7. Open the S1D13506 workspace.

From the Tornado toolbar, select File->Open Workspace...->Existing->Browse... and select the file “x:\13506\8bpp\13506.wsp” (or “x:\13506\16bpp\13506.wsp”).

8. Add support for single line comments.

The WindML v2.0 display driver source code uses single line comment notation, “//”, rather than the ANSI conventional comments, “/*...*/”.

To add support for single line comments follow these steps:

   a. In the Tornado “Workspace Views” window, click on the “Builds” tab.

   b. Expand the “8bpp Builds” (or “16bpp Builds”) view by clicking on the “+” next to it. The expanded view will contain the item “default”. Right-click on “default” and select “Properties...”. A “Properties:” window will appear.

   c. Select the “C/C++ compiler” tab to display the command switches used in the build. Remove the “-ansi” switch from the line that contains “-g -mpentium -ansi -nostdinc -DRW_MULTI_THREAD”.
(Refer to GNU ToolKit user’s guide for details)

9. Compile the VxWorks image.

Select the “Builds” tab in the Tornado “Workspace Views” window.

Right-click on “8bpp files” (or “16bpp files”) and select “Dependencies...”. Click on “OK” to regenerate project file dependencies for “All Project files”.

Right-click on “8bpp files” (or “16bpp files”) and select “ReBuild All(vxWorks)” to build VxWorks.

10. Copy the VxWorks file to the diskette.

From a command prompt or through the Windows interface, copy the file “x:\13506\8bpp\default\vxWorks” (or “x:\13506\16bpp\default\vxWorks”) to the bootable disk created in step 4.

11. Start the VxWorks demo.

Boot the target PC with the VxWorks bootable diskette to run the UGLDEMO automatically.
Wind River UGL v1.2 Display Drivers

The Wind River UGL v1.2 display drivers for the S1D13506 Color LCD/CRT/TV Controller are intended as “reference” source code for OEMs developing for Wind River’s UGL v1.2. The drivers provide support for both 8 and 16 bit-per-pixel color depths. The source code is written for portability and contains functionality for most features of the S1D13506. Source code modification is required to provide a smaller, more efficient driver for mass production (e.g. TV support may be removed for products not requiring TV).

The UGL display drivers are designed around a common configuration include file called mode0.h which is generated by the configuration utility 13506CFG. This design allows for easy customization of display type, clocks, addresses, rotation, etc. by OEMs. For further information on 13506CFG, see the 13506CFG Configuration Program User Manual, document number X25B-B-001-xx.

This document and the source code for the UGL display drivers are updated as appropriate. Please check the Epson Electronics America website at http://www.eea.epson.com or the Epson Research and Development website at http://www.erd.epson.com for the latest revisions before beginning any development.

We appreciate your comments on our documentation. Please contact us via e-mail at documentation@erd.epson.com.
Building a UGL v1.2 Display Driver

The following instructions produce a bootable disk that automatically starts the UGL demo software. These instructions assume that the Wind River Tornado platform is correctly installed.

Note
For the example steps where the drive letter is given as “x:”. Substitute “x” with the drive letter that your development environment is on.

1. Create a working directory and unzip the UGL display driver into it

   Using a command prompt or GUI interface create a new directory (e.g. x:\13506).
   Unzip the file 13506ugl.zip to the newly created working directory. The files will be unzipped to the directories “x:\13506\8bpp” and “x:\13506\16bpp”.

2. Configure for the target execution model.

   This example build creates a VxWorks image that fits onto and boots from a single floppy diskette. In order for the VxWorks image to fit on the disk certain modifications are required.

   Replace the file “x:\Tornado\target\config\pcPentium\config.h” with the file “x:\13506\8bpp\File\config.h” (or “x:\13506\16bpp\File\config.h”). The new config.h file removes networking components and configures the build image for booting from a floppy disk.

   Note
   Rather than simply replacing the original config.h file, rename it so the file can be kept for reference purposes.

3. Build a boot ROM image.

   From the Tornado tool bar, select Build -> Build Boot ROM. Select “pcPentium” as the BSP and “bootrom_uncmp” as the image.

4. Create a bootable disk (in drive A:).

   From a command prompt in the directory “x:\Tornado\target\config\pcPentium” type
   mkboot a: bootrom_uncmp

5. If necessary, generate a new mode0.h configuration file.

   The file mode0.h contains the register values required to set the screen resolution, color depth (bpp), display type, active display (LCD/CRT/TV), rotation, etc. The mode0.h, included with the drivers, sets the display for 640x480 60 Hz output to a CRT display.

   If this setting is inappropriate then mode0.h must be regenerated. The configuration program 13506CFG can be used to build a new mode0.h file. If building for 8 bpp, place the new mode0.h file in “x:\13506\8bpp\File”. If building for 16 bpp, place the new mode0.h file in “x:\13506\16bpp\File”.
Note

Mode0.h should be created using the configuration utility 13506CFG. For more information on 13506CFG, see the 13506CFG Configuration Program User Manual, document number X25B-B-001-xx available at www.erd.epson.com.

6. Open the S1D13506 workspace.

From the Tornado toolbar, select File->Open Workspace...->Existing->Browse... and select the file “x:\13506\8bpp\13506.wsp” (or “x:\13506\16bpp\13506.wsp”).

7. Add support for single line comments.

The UGL v1.2 display driver source code uses single line comment notation, “/”, rather than the ANSI conventional comments, “/ * . . . */”.

To add support for single line comments follow these steps:

a. In the Tornado “Workspace” window, click on the “Builds” tab.

b. Expand the “8bpp Builds” (or “16bpp Builds”) view by clicking on the “+” next to it. The expanded view will contain the item “default”. Right-click on “default” and select “Properties...”. A properties window will appear.

c. Select the “C/C++ compiler” tab to display the command switches used in the build. Remove the “-ansi” switch from the line that contains “-g -mpentium -ansi -nostdinc -DRW_MULTI_THREAD”. (Refer to GNU ToolKit user's guide for details)

8. Compile the VxWorks image.

Select the “Files” tab in the Tornado “Workspace” window.

Right-click on “8bpp files” (or “16bpp files”) and select “Dependencies...”. Click on “OK” to regenerate project file dependencies for “All Project files”.

Right-click on “8bpp files” (or “16bpp files”) and select “ReBuild All(vxWorks)” to build VxWorks.

9. Copy the VxWorks file to the diskette.

From a command prompt or through the Windows interface, copy the file “x:\13506\8bpp\default\vxWorks” (or “x:\13506\16bpp\default\vxWorks”) to the bootable disk created in step 4.

10. Start the VxWorks demo.

Boot the target PC with the VxWorks bootable diskette to run the UGLDEMO automatically.

QNX Photon v2.0 Display Driver

The Photon v2.0 display drivers for the S1D13506 Color LCD/CRT/TV Controller are intended as “reference” source code for OEMs developing for QNX platforms. The driver package provides support for 8 and 16 bit-per-pixel color depths. The source code is written for portability and contains functionality for most features of the S1D13506. Source code modification is required to provide a smaller driver for mass production.

The current revision of the driver is designed for use with either QNX RTP or QNX4 from the latest product CD (Dec. 99).

The Photon v2.0 display driver is designed around a common configuration include file called S1D13506.h, which is generated by the configuration utility 13506CFG. This design allows for easy customization of display type, clocks, decode addresses, etc. by OEMs. For further information on 13506CFG, see the 13506CFG Configuration Program User Manual, document number X25B-B-001-xx.

Note
The QNX display drivers are provided as “reference” source code only. They are intended to provide a basis for OEMs to develop their own drivers for QNX Photon v2.0.

This document and the source code for the QNX display drivers are updated as appropriate. Please check the Epson Electronics America website at http://www.eea.epson.com or the Epson Research and Development website at http://www.erd.epson.com for the latest revisions before beginning any development.

We appreciate your comments on our documentation. Please contact us via e-mail at documentation@erd.epson.com.
Building the Photon v2.0 Display Driver

The following steps build the Photon v2.0 display driver and integrate it into the QNX operating system. These instructions assume the QNX developer environment is correctly installed and the developer is familiar with building for the QNX operating system.

Unpack the Graphics Driver Development Kit Archive

1. Install the QNX ddk package using the Package Manager utility.

   For information about the Drivers Development Kit contact QNX directly.

2. Once the ddk package is installed, copy the directory tree /usr/scr/gddk_v1.0 into the Project directory.

3. Change directory to Project/gddk_1.0/devg.

4. Unpack the display driver files using the commands:

   #gunzip S1D13506.tar.gz
   #tar –xvf S1D13506.tar

   This unpacks the files into the directory Project/gddk_1.0/devg/S1D13506.

Configure the Driver

The files s1d13506_16.h and s1d13506_8.h contain register values required to set the screen resolution, color depth (bpp), display type, etc. The s1d13506.h file included with the drivers may not contain applicable values and must be regenerated. The configuration program 13506CFG can be used to build new s1d13506_16.h and s1d13506_8.h files.

Note
S1d13506.h should be created using the configuration utility 13506CFG. For more information on 13506CFG, see the 13506CFG Configuration Program User Manual, document number X25B-B-001-xx available at www.erd.epson.com.

Build the Driver

The first time the driver is built, the following command ensures that all drivers and required libraries are built. At the root of the Project source tree, type make.

Note
To build drivers for X86 NTO type ‘OSLIST=nto CPULIST=x86 make’.

Further builds do not require all libraries to be re-built. To build only the S1D13506 display driver, change to the directory gddk_1.0/devg/S1D13506 and type make.
Installing the Driver

The build step produces two library images:

- lib/disputil/nto/x86/so/libdisputil.so
- lib/ffb/nto/x86/so/libffb.so

For the loader to locate them, the files need to be renamed and copied to the lib directory.

1. Rename libdisputil.so to libdisputil.so.1 and libffb.so to libffb.so.1.
2. Copy the files new files libdisputil.so.1 and libffb.so.1 to the directory /usr/lib.
3. Copy the file devg-S1D13506.so to the /lib/dll directory.

**Note**
To locate the file devg-S1D13506.so, watch the output of the ‘true’ command during the makefile build.

4. Modify the trap file graphics-modes in the /etc/system/config directory by inserting the following lines at the top of the file.

   io-graphics -dldevg-S1D13506.so -g640x480x8 -I0 -d0x0,0x0;#640,480,8 Epson
   io-graphics -dldevg-S1D13506.so -g640x480x16 -I0 -d0x0,0x0;#640,480,16 Epson

Run the Driver

**Note**
For the remaining steps the S5U13506B00C evaluation board must be installed on the test platform.

It is recommended that the driver be verified before starting QNX with the S1D13506 as the primary display. To verify the driver:

1. Copy the data file from the services/graphics/tests/bench directory to the current directory. Use test8.raw for 8-bpp and test16.raw for 16-bpp.
2. Type the following command at the root of the Project source tree (gddk_v1.00 directory):

   services/graphics/tests/bench/nto/x86/o/bench -dlhardware/devg/S1D13506/nto/x86/dll/devg-S1D13506.so -mW,H,C,F -d0x0,0x0

Where:
- W is the configured width of the display
- H is the configured height of the display
- C is the color depth in bpp (either 8 or 16)
- F is the configured frame rate
This command starts the bench utility which will initialize the driver as the secondary display and exercise the drivers main functions. If the display appears satisfactory, restart QNX Photon and the restart will result in the S1D13506 display driver becoming the primary display device.

**Comments**

- To restore the display driver to the default, comment out changes made to the trap file graphics-trapfile.
THIS PAGE LEFT BLANK
WINDOWS® CE 3.x DISPLAY DRIVERS

The Windows CE 3.x display driver is designed to support the S1D13506 Color LCD/CRT/TV Controller running the Microsoft Windows CE operating system, version 3.0. The driver is capable of: 4, 8 and 16 bit-per-pixel landscape modes (no rotation), and 8 and 16 bit-per-pixel SwivelView™ 90 degree, 180 degree and 270 degree modes.

This document and the source code for the Windows CE drivers are updated as appropriate. Before beginning any development, please check the Epson Electronics America Website at www.eea.epson.com or the Epson Research and Development Website at www.erd.epson.com for the latest revisions.

We appreciate your comments on our documentation. Please contact us via email at techpubs@erd.epson.com.
Example Driver Builds

The following sections describe how to build the Windows CE display driver for:

1. Windows CE Platform Builder 3.00 using the GUI interface.
2. Windows CE Platform Builder 3.00 using the command-line interface.

In all examples “x:” refers to the drive letter where Platform Builder is installed.

Build for CEPC (X86) on Windows CE Platform Builder 3.00 using the GUI Interface

1. Install Microsoft Windows 2000 Professional, or Windows NT Workstation version 4.0 with Service Pack 5 or later.
2. Install Windows CE Platform Builder 3.00.
4. Create a new project.
   a. Select File | New.
   b. In the dialog box, select the Platforms tab.
   c. In the platforms dialog box, select “WCE Platform”, set a location for the project (such as x:\myproject), set the platform name (such as myplatform), and set the Processors to “Win32 (WCE x86)”.
   d. Click the OK button.
   e. In the dialog box “WCE Platform - Step 1 of 2”, select CEPC.
   f. Click the Next button.
   g. In the dialog box “WCE Platform - Step 2 of 2”, select Maximum OS (Maxall).
   h. Click the Finish button.
   i. In the dialog box “New Platform Information”, click the OK button.
5. Set the active configuration to “Win32 (WCE x86) Release”.
   a. From the Build menu, select “Set Active Configuration”.
   b. Select “MYPLATFORM - Win32 (WCE x86) Release”.
   c. Click the OK button.
6. Add the environment variable CEPC_DDI_S1D13506.
   a. From the Platform menu, select “Settings”.
   b. Select the “Environment” tab.
   c. In the Variable box, type “CEPC_DDI_S1D13506”.
d. In the Value box, type “1”.

e. Click the Set button.

f. Click the OK button.

7. Create a new directory S1D13506, under x:\wince300\platform\cepc\drivers\display, and copy the S1D13506 driver source code into this new directory.

8. Add the S1D13506 driver component.

a. From the Platform menu, select “Insert | User Component”.

b. Set “Files of type:” to “All Files (*.*)”.

c. Select the file x:\wince300\platform\cepc\drivers\display\S1D13506\sources.

d. In the “User Component Target File” dialog box, select browse and then select the path and the file name of “sources”.

9. Delete the component “ddi_flat”.

a. In the Platform window, select the ComponentView tab.

b. Show the tree for MYPLATFORM components by clicking on the ‘+’ sign at the root of the tree.

c. Right-click on the ddi_flat component.

d. Select “Delete”.

e. From the File menu, select “Save Workspace”.

10. From the Platform window, click on ParameterView Tab. Show the tree for MYPLATFORM Parameters by clicking on the ‘+’ sign at the root of the tree. Expand the the WINCE300 tree and then click on “Hardware Specific Files” and then double click on “PLATFORM.BIB”. Edit the file the PLATFORM.BIB file and make the following two changes:

a. Insert the following text after the line “IF ODO_NODISPLAY !”:

   IF CEPC_DDI_S1D13506
       ddi.dll $(FLATRELEASEDIR)S1D13506.dll NK SH
   ENDIF

b. Find the section shown below, and insert the lines as marked:

   IF CEPC_DDI_FLAT !
   IF CEPC_DDI_S1D13506!
   IF CEPC_DDI_S3VIRGE !
   IF CEPC_DDI_CT655X !
   IF CEPC_DDI_VGA8BPP !
   IF CEPC_DDI_S3TRIO64 !
   IF CEPC_DDI_ATI !

   :Insert this line
11. Modify MODE0.H.

The file MODE0.H (located in x:\wince300\platform\cepc\drivers\display\S1D13506) contains the register values required to set the screen resolution, color depth (bpp), display type, active display (LCD/CRT/TV), display rotation, etc.

Before building the display driver, refer to the descriptions in the file MODE0.H for the default settings of the console driver. If the default does not match the configuration you are building for then MODE0.H will have to be regenerated with the correct information.

Use the program 13506CFG to generate the header file. For information on how to use 13506CFG, refer to the 13506CFG Configuration Program User Manual, document number X25B-B-001-xx, available at www.erd.epson.com

After selecting the desired configuration, export the file as a “C Header File for S1D13506 WinCE Drivers”. Save the new configuration as MODE0.H in the \wince300\platform\cepc\drivers\display, replacing the original configuration file.

12. From the Platform window, click on ParameterView Tab. Show the tree for MY-PLATFORM Parameters by clicking on the ‘+’ sign at the root of the tree. Expand the WINCE300 tree and click on “Hardware Specific Files”, then double click on “PLATFORM.REG”. Edit the file PLATFORM.REG to match the screen resolution, color depth, and rotation information in MODE.H.

For example, the display driver section of PLATFORM.REG should be as follows when using a 640x480 LCD panel with a color depth of 8 bpp and a SwivelView mode of 0° (landscape):

; Default for EPSON Display Driver
; 640x480 at 8 bits/pixel, LCD display, no rotation
; Useful Hex Values
; 1024=0x400, 768=0x300 640=0x280 480=0x1E0 320=140 240=0xF0
[HKEY_LOCAL_MACHINE\Drivers\Display\S1D13506]
“Width”=dword:280
“Height”=dword:1E0
“Bpp”=dword:8
“ActiveDisp”=dword:1
“Rotation”=dword:0

13. From the Build menu, select “Rebuild Platform” to generate a Windows CE image file (NK.BIN) in the project directory
x:\myproject\myplatform\reldir\x86_release\nk.bin.

Build for CEPC (X86) on Windows CE Platform Builder 3.00 using the Command-Line Interface

1. Install Microsoft Windows 2000 Professional, or Windows NT Workstation version 4.0 with Service Pack 5 or later.

2. Install Windows CE Platform Builder 3.00.

3. Create a batch file called x:\wince300\cepath.bat. Put the following in cepath.bat:
   x:
cd \wince300\public\common\oak\misc
call wince x86 i486 CE MAXALL CEPC
set IMGNODEBUGGER=1
set WINCEREL=1
set CEPC_DDI_S1D13506=1

4. Generate the build environment by calling cepath.bat.

5. Create a new folder called S1D13506 under x:\wince300\platform\cepc\drivers\display, and copy the S1D13506 driver source code into x:\wince300\platform\cepc\drivers\display\S1D13506.

6. Edit the file x:\wince300\platform\cepc\drivers\display\dirs and add S1D13506 into the list of directories.

7. Edit the file x:\wince300\platform\cepc\files\platform.bib and make the following two changes:
   a. Insert the following text after the line “IF ODO_NODISPLAY !”:
      IF CEPC_DDI_S1D13506
         ddi.dll $(FLATRELEASEDIR)\S1D13506.dll  NK SH
      ENDIF
   b. Find the section shown below, and insert the lines as marked:
      IF CEPC_DDI_FLAT !
      IF CEPC_DDI_S1D13506!
      ;Insert this line
      IF CEPC_DDI_S3VIRGE !
      IF CEPC_DDI_CT655X !
      IF CEPC_DDI_VGA8BPP !
      IF CEPC_DDI_S3TRIO64 !
      IF CEPC_DDI_ATI !
8. Modify MODE0.H.

The file MODE0.H (located in x:\wince300\platform\cepc\drivers\display\S1D13506) contains the register values required to set the screen resolution, color depth (bpp), display type, active display (LCD/CRT/TV), display rotation, etc.

Before building the display driver, refer to the descriptions in the file MODE0.H for the default settings of the display driver. If the default does not match the configuration you are building for then MODE0.H will have to be regenerated with the correct information.

Use the program 13506CFG to generate the header file. For information on how to use 13506CFG, refer to the 13506CFG Configuration Program User Manual, document number X25B-B-001-xx, available at www.erd.epson.com

After selecting the desired configuration, export the file as a “C Header File for S1D13506 WinCE Drivers”. Save the new configuration as MODE0.H in the \wince300\platform\cepc\drivers\display, replacing the original configuration file.

9. Edit the file PLATFORM.REG to match the screen resolution, color depth, and rotation information in MODE.H. PLATFORM.REG is located in x:\wince300\platform\cepc\files.

For example, the display driver section of PLATFORM.REG should be as follows when using a 640x480 LCD panel with a color depth of 8 bpp and a SwivelView mode of 0° (landscape):

; Default for EPSON Display Driver
; 640x480 at 8 bits/pixel, LCD display, no rotation
; Useful Hex Values
; 1024=0x400, 768=0x300 640=0x280 480=0x1E0 320=140 240=0xF0
[HKEY_LOCAL_MACHINE\Drivers\Display\S1D13506]
“Width”=dword:280
“Height”=dword:1E0
“Bpp”=dword:8
“ActiveDisp”=dword:1
“Rotation”=dword:0
10. Delete all the files in the x:\wince300\release directory and delete the file x:\wince300\platform\cepc\*.bif

11. Type BLDDEMO <ENTER> at the command prompt to generate a Windows CE image file. The file generated will be x:\wince300\release\nk.bin.
Installation for CEPC Environment

Once the NK.BIN file is built, the CEPC environment can be started by booting either from a floppy or hard drive configured with a Windows 9x operating system. The two methods are described below.

1. To start CEPC after booting from a floppy drive:
   a. Create a bootable floppy disk.
   b. Edit CONFIG.SYS on the floppy disk to contain only the following line:
      
      device=a:\himem.sys
   c. Edit AUTOEXEC.BAT on the floppy disk to contain the following lines:
      
      mode com1:9600,n,8,1
      loadcepc /B:9600 /C:1 c:\nk.bin
   d. Copy LOADCEPC.EXE and HIMEM.SYS to the bootable floppy disk. Search for the loadCEPC utility in your Windows CE directories.
   e. Copy NK.BIN to c:\
   f. Boot the system from the bootable floppy disk.

2. To start CEPC after booting from a hard drive:
   a. Copy LOADCEPC.EXE to C:\. Search for the loadCEPC utility in your Windows CE directories.
   b. Edit CONFIG.SYS on the hard drive to contain only the following line:
      
      device=c:\himem.sys
   c. Edit AUTOEXEC.BAT on the hard drive to contain the following lines:
      
      mode com1:9600,n,8,1
      loadcepc /B:9600 /C:1 c:\nk.bin
   d. Copy NK.BIN and HIMEM.SYS to c:\.
   e. Boot the system.
Configuration

There are several issues to consider when configuring the display driver. The issues cover debugging support, register initialization values and memory allocation. Each of these issues is discussed in the following sections.

Compile Switches

There are several switches, specific to the S1D13506 display driver, which affect the display driver.

The switches are added or removed from the compile options in the file SOURCES.

WINCEVER

This option is automatically set to the numerical version of WinCE for version 2.12 or later. If the environment variable, _WINCEOSVER is not defined, then WINCEVER will default 2.11. The S1D display driver may test against this option to support different WinCE version-specific features.

EnablePreferVmem

This option enables the use of off-screen video memory. When this option is enabled, WinCE can optimize some BLT operations by using off-screen video memory to store images. You may need to disable this option for systems with 512K bytes of video memory and VGA (640x480) panels.

Enable2DC

This option enables the S1D13506 display driver to support an alternate device context. This may be useful for applications such as Pocket PowerPoint, which can display a different image on a display device other than the primary display. The driver support for this is still under development and is UNTESTED.

Future releases of the S1D13506 display drivers will have full support for alternate displays.

EnableDC2Hwblt

This option enables hardware BLT acceleration on the alternate display (see Enable2DC). This option is currently unused and will be fully supported in future releases of the S1D13506 display drivers.
ENABLE_CLOCK_CHIP

This option is used to enable support for the ICD2061A clock generator. This clock chip is used on the S5U13506B00C evaluation board. The S1D13506 display drivers can program the clock chip to support the frequencies required in the MODE tables.

If you are not using the S5U13506B00C evaluation adapter, you should disable this option.

ENABLE_ANTIALIASED_FONTS

This option enables the display driver support of antialiased fonts in WinCE. Fonts created with the ANTIALIASED_QUALITY attribute will be drawn with font smoothing.

If you want all fonts to be antialiased by default, add the following line to PLATFORM.REG: [HKEY_LOCAL_MACHINE\SYSTEM\GDI\Fontsmoothing]. This registry option causes WinCE to draw all fonts with smoothing.

Font smoothing is only applicable to 16bpp mode.

EpsonMessages

This debugging option enables the display of EPSON-specific debug messages. These debug message are sent to the serial debugging port. This option should be disabled unless you are debugging the display driver, as they will significantly impact the performance of the display driver.

DEBUG_MONITOR

This option enables the use of the debug monitor. The debug monitor can be invoked when the display driver is first loaded and can be used to view registers, and perform a few debugging tasks. The debug monitor is still under development and is UNTESTED.

This option should remain disabled unless you are performing specific debugging tasks that require the debug monitor.

MonoPanel

This option is intended for the support of monochrome panels only.

The option causes palette colors to be grayscaled for correct display on a mono panel. For use with color panels this option should not be enabled.

TEST_BITMAP

This option allows the debug monitor to display a test bitmap. This bitmap is big and will make the display driver considerably larger. The flag DEBUG_MONITOR must also be enabled for this option to work.
This option should be disabled unless the image is required for debugging.

DEBUG_BLT

This option enables special BLT debugging messages on the debugging serial port. This option, when enabled, will drastically impact display driver performance, and should only be used to track down failures in the BLT operations.

This option should be disabled unless doing BLT debugging.

FILL_DELETED_OFFSCREEN_SURFACE

This option enables special debugging code that will fill (blank) off-screen rectangular surfaces when they are destructed. This option is only useful if EnablePreferVmem is also enabled. When enabled, off-screen surfaces are filled with a solid color when they are deleted. If any code then attempts to reuse the deleted off screen surface, the results should show up as errors on the primary display.

This option should be disabled unless doing debugging.

Mode File

The MODE tables (contained in files MODE0.H, MODE1.H, MODE2.H . . . ) contain register information to control the desired display mode. The MODE tables must be generated by the configuration program 13506CFG.EXE. The display driver comes with example MODE tables.

By default, only MODE0.H is used by the display driver. New mode tables can be created using the 13506CFG program. Edit the #include section of MODE.H to add the new mode table.

If you only support a single display mode, you do not need to add any information to the WinCE registry. If, however, you support more that one display mode, you should create registry values (see below) that will establish the initial display mode. If your display driver contains multiple mode tables, and if you do not add any registry values, the display driver will default to the first mode table in your list.

To select which display mode the display driver should use upon boot, add the following lines to your PLATFORM.REG file:

[HKEY_LOCAL_MACHINE\Drivers\Display\S1D13506]

“Width”=dword:280
“Height”=dword:1E0
“Bpp”=dword:8
“Rotation”=dword:0
“RefreshRate”=dword:3C
“Flags”=dword:2
Note that all dword values are in hexadecimal, therefore $280h = 640$, $1E0h = 480$, and $3Ch = 60$. The value for “Flags” should be 1 (LCD), 2 (CRT), or 3 (both LCD and CRT). When the display driver starts, it will read these values in the registry and attempt to match a mode table against them. All values must be present and valid for a match to occur, otherwise the display driver will default to the first mode table in your list.

A WinCE desktop application (or control panel applet) can change these registry values, and the display driver will select a different mode upon warmboot. This allows the display driver to support different display configurations and/or orientations. An example application that controls these registry values will be made available upon the next release of the display driver; preliminary alpha code is available by special request.

Resource Management Issues

The Windows CE 3.0 OEM must deal with certain display driver issues relevant to Windows CE 3.0. These issues require the OEM balance factors such as: system vs. display memory utilization, video performance, and power off capabilities.

The section “Simple Display Driver Configuration” on page 16 provides a configuration which should work with most Windows CE platforms. This section is only intended as a means of getting started. Once the developer has a functional system, it is recommended to optimize the display driver configuration as described below in “Description of Windows CE Display Driver Issues”.

Description of Windows CE Display Driver Issues

The following are some issues to consider when configuring the display driver to work with Windows CE:

1. When Windows CE enters the Suspend state (power-off), the LCD controller and display memory may lose power, depending on how the system is designed. If display memory loses power, all images stored in display memory are lost.

   If power-off/power-on features are required, the OEM has several options:

   • If display memory power is turned off, add code to the display driver to save any images in display memory to system memory before power-off, and add code to restore these images after power-on.

   • If display memory power is turned off, instruct Windows CE to redraw all images upon power-on. Unfortunately it is not possible to instruct Windows CE to redraw any off-screen images, such as icons, slider bars, etc., so in this case the OEM must also configure the display driver to never use off-screen memory.

   • Ensure that display memory never loses power.

2. Using off-screen display memory significantly improves display performance. For example, slider bars appear more smooth when using off-screen memory. To enable or disable the use of off-screen memory, edit the file: x:\wince300\platform\cepc\driv-
ers\display\S1D13506\sources. In SOURCES, there is a line which, when uncommented, will instruct Windows CE to use off-screen display memory (if sufficient display memory is available):

CDEFINES=$(CDEFINES) -DEnablePreferVmem

3. In the file PROJECT.REG under CE 3.0, there is a key called PORepaint (search the Windows CE directories for PROJECT.REG). PORepaint is relevant when the Suspend state is entered or exited. PORepaint can be set to 0, 1, or 2 as described below:

a. PORepaint=0
   - This mode tells Windows CE not to save or restore display memory on suspend or resume.
   - Since display data is not saved and not repainted, this is the FASTEST mode.
   - Main display data in display memory must NOT be corrupted or lost on suspend. The memory clock must remain running.
   - Off-screen data in display memory must NOT be corrupted or lost on suspend. The memory clock must remain running.
   - This mode cannot be used if power to the display memory is turned off.

b. PORepaint=1
   - This is the default mode for Windows CE.
   - This mode tells Windows CE to save the main display data to the system memory on suspend.
   - This mode is used if display memory power is going to be turned off when the system is suspended, and there is enough system memory to save the image.
   - Any off-screen data in display memory is LOST when suspended. Therefore off-screen memory usage must either be disabled in the display driver (i.e: EnablePreferVmem not defined in SOURCES file), or new OEM-specific code must be added to the display driver to save off-screen data to system memory when the system is suspended, and restored when resumed.
   - If off-screen data is used (provided that the OEM has provided code to save off-screen data when the system suspends), additional code must be added to the display driver’s surface allocation routine to prevent the display driver from allocating the “main memory save region” in display memory. When WinCE OS attempts to allocate a buffer to save the main display data, WinCE OS marks the allocation request as preferring display memory. We believe this is incorrect. Code must be added to prevent this specific allocation from being allocated in display memory - it MUST be allocated from system memory.
   - Since the main display data is copied to system memory on suspend, and then simply copied back on resume, this mode is FAST, but not as fast as mode 0.

c. PORepaint=2
- This mode tells WinCE to not save the main display data on suspend, and causes WinCE to REPAINT the main display on resume.

- This mode is used if display memory power is going to be turned off when the system is suspended, and there is not enough system memory to save the image.

- Any off-screen data in display memory is LOST, and since there is insufficient system memory to save display data, off-screen memory usage MUST be disabled.

- When the system is resumed, WinCE instructs all running applications to repaint themselves. This is the SLOWEST of the three modes.

**Simple Display Driver Configuration**

The following display driver configuration should work with most platforms running Windows CE. This configuration disables the use of off-screen display memory and forces the system to redraw the main display upon power-on.

1. This step disables the use of off-screen display memory.
   Edit the file x:\wince300\platform\cepc\drivers\display\S1D13506\sources and change the line
   
   `CDEFINES=$(CDEFINES) -DEnablePreferVmem`
   
   to
   
   `#CDEFINES=$(CDEFINES) -DEnablePreferVmem`

2. This step causes the system to redraw the main display upon power-on. This step is only required if display memory loses power when Windows CE is shut down. If display memory is kept powered up (set the S1D13506 in powersave mode), then the display data will be maintained and this step can be skipped.

   Search for the file PROJECT.REG in your Windows CE directories, and inside PROJECT.REG find the key PORepaint. Change PORepaint as follows:

   “PORepaint”=dword:2
Comments

- The display driver is CPU independent, allowing use of the driver for several Windows CE Platform Builder supported platforms.

- 13506CFG assumes PCI addressing for the S5U13506B00C evaluation board. This means that the display driver will automatically locate the S1D13506 by scanning the PCI bus (currently only supported for the CEPC platform). If you select the address option “Other” and fill in your own custom addresses for the registers and video memory, then the display driver will not scan the PCI bus and will use the specific addresses you have chosen.

- If you are running the display driver on hardware other than the S5U13506B00C evaluation board, you must ensure that your hardware provides the correct clock frequencies for CLKI and CLKI2. The 13506CFG program defaults CLKI to 25.175MHz and CLKI2 to 14.318MHz. The 13506CFG program also defaults BUSCLK to the PCI clock of 33.333MHz.

  On the evaluation board, the display driver will correctly program the clock chip to support the CLKI and CLKI2 frequencies, and BUSCLK is derived from the PCI clock. On customer hardware, you must ensure that the clocks you provide to all clock inputs match the settings you chose in the Clocks tab of the 13506CFG program.

  If you run the S1D13506 with a single clock source, make sure your clock sources for LCD, CRT, MediaPlug, and MCLK are correctly set to use the correct clock input source (typically BUSCLK). Also ensure that you enable the clock dividers as required for different display hardware.

- If you are running 13506CFG.EXE to produce multiple MODE tables, make sure you change the Mode Number in the WinCE tab for each mode table you generate. The display driver supports multiple mode tables, but only if each mode table has a unique mode number.

- At this time, the drivers have been tested on the x86 CPUs and have been built with Platform Builder v3.00.
S1D13XXX 32-Bit Windows Device Driver Installation Guide

This manual describes the installation of the Windows 9x/ME/NT 4.0/2000 device drivers for the S5U13xxxB00x series of Epson Evaluation Boards.

The file S1D13XXX.VXD is required for using the Epson supplied Intel32 evaluation and test programs for the S1D13xxx family of LCD controllers with Windows 9x/ME.

The file S1D13XXX.SYS is required for using the Epson supplied Intel32 evaluation and test programs for the S1D13xxx family of LCD controllers with Windows NT 4.0/2000.

The file S1D13XXX.INF is the install script.

For updated drivers, ask your Sales Representative or visit Epson Electronics America on the World Wide Web at www.eea.epson.com.

Driver Requirements

Video Controller : S1D13xxx
Display Type : N/A
BIOS : N/A
DOS Program : No
Dos Version : N/A
Windows Program : Yes, Windows 9x/ME/NT 4.0/2000 device driver
Windows DOS Box : N/A
Windows Full Screen : N/A
OS/2 : N/A

Installation

Windows NT Version 4.0

All evaluation boards require the driver to be installed as follows.

1. Install the evaluation board in the computer and boot the computer.

2. Copy the files S1D13XXX.INF and S1D13XXX.SYS to a directory on a local hard drive.

3. Right click your mouse on the file S1D13XXX.INF and select INSTALL from the menu.

4. Windows will install the device driver and ask you to restart.
Windows 2000

All PCI Bus Evaluation Cards

1. Install the evaluation board in the computer and boot the computer.

2. Windows will detect the new hardware as a new PCI Device and bring up the FOUND
NEW HARDWARE dialog box.

3. Click NEXT.

4. The New Hardware Wizard will bring up the dialog box to search for a suitable driver.

5. Click NEXT.

6. When Windows does not find the driver it will allow you to specify the location of it.
   Type the driver location or select BROWSE to find it.

7. Click NEXT.

8. Windows 2000 will open the installation file and show the option EPSON PCI Bridge
   Card. Select this file and click OPEN.

9. Windows then shows the path to the file. Click OK.

10. Click NEXT.

11. Click FINISH.

All ISA Bus Evaluation Cards

1. Install the evaluation board in the computer and boot the computer.

2. Go to the CONTROL PANEL and select ADD/REMOVE HARDWARE, click NEXT.

3. Select ADD/TROUBLESHOOT A DEVICE, and click NEXT. Windows 2000 will
   attempt to detect any new plug and play device and fail.

4. The CHOOSE HARDWARE DEVICE dialog box appears. Select ADD NEW
   HARDWARE and click NEXT.

5. Select NO I WANT TO SELECT FROM A LIST and click NEXT.

6. Select OTHER DEVICE from the list and click NEXT.

7. Click HAVE DISK.

8. Specify the location of the driver files, select the S1D13XXX INF file and click
   OPEN.

9. Click OK.
Windows 98/ME

All PCI Bus Evaluation Cards

1. Install the evaluation board in the computer and boot the computer.
2. Windows will detect the new hardware as a new PCI Device and bring up the ADD NEW HARDWARE dialog box.
3. Click NEXT.
4. Windows will look for the driver. When Windows does not find the driver it will allow you to specify the location of it. Type the driver location or select BROWSE to find it.
5. Click NEXT.
6. Windows will open the installation file and show the option EPSON PCI Bridge Card.
7. Click FINISH.

All ISA Bus Evaluation Cards

1. Install the evaluation board in the computer and boot the computer.
2. Go to the CONTROL PANEL and double-click on ADD NEW HARDWARE to launch the ADD NEW HARDWARE WIZARD. Click NEXT.
3. Windows will attempt to detect any new plug and play device and fail. Click NEXT.
4. Windows will ask you to let it detect the hardware, or allow you to select from a list. Select NO, I WANT TO SELECT THE HARDWARE FROM A LIST and click NEXT.
5. From the list select OTHER DEVICES and click NEXT.
6. Click HAVE DISK and type the path to the driver files, or select browse to find the driver.
7. Click OK.
8. The driver will be identified as EPSON PCI Bridge Card. Click NEXT.
9. Click FINISH.
Windows 95 OSR2

All PCI Bus Evaluation Cards

1. Install the evaluation board in the computer and boot the computer.

2. Windows will detect the card as a new PCI Device and launch the UPDATE DEVICE DRIVER wizard.

If The Driver is on Floppy Disk

3. Place the disk into drive A: and click NEXT.

4. Windows will find the EPSON PCI Bridge Card.

5. Click FINISH to install the driver.

6. Windows will ask you to restart the system.

If The Driver is not on Floppy Disk

3. Click NEXT, Windows will search the floppy drive and fail.

4. Windows will attempt to load the new hardware as a Standard VGA Card.

5. Click CANCEL. The Driver must be loaded from the CONTROL PANEL under ADD/NEW HARDWARE.

6. Select NO for Windows to DETECT NEW HARDWARE.

7. Click NEXT.

8. Select OTHER DEVICES from HARDWARE TYPE and Click NEXT.

9. Click HAVE DISK.

10. Specify the location of the driver and click OK.

11. Click OK.

12. EPSON PCI Bridge Card will appear in the list.

13. Click NEXT.

14. Windows will install the driver.

15. Click FINISH.

16. Windows will ask you to restart the system.

17. Windows will re-detect the card and ask you to restart the system.
All ISA Bus Evaluation Cards

1. Install the evaluation board in the computer and boot the computer.
2. Go to the CONTROL PANEL and select ADD NEW HARDWARE.
3. Click NEXT.
4. Select NO and click NEXT.
5. Select OTHER DEVICES and click NEXT.
6. Click Have Disk.
7. Specify the location of the driver files and click OK.
8. Click Next.
9. Click Finish.

Previous Versions of Windows 95

All PCI Bus Evaluation Cards

1. Install the evaluation board in the computer and boot the computer.
2. Windows will detect the card.
3. Select DRIVER FROM DISK PROVIDED BY MANUFACTURER.
4. Click OK.
5. Specify a path to the location of the driver files.
6. Click OK.
7. Windows will find the S1D13XXX.INF file.
8. Click OK.
9. Click OK and Windows will install the driver.
All ISA Bus Evaluation Cards

1. Install the evaluation board in the computer and boot the computer.
2. Go to the CONTROL PANEL and select ADD NEW HARDWARE.
3. Click NEXT.
4. Select NO and click NEXT.
5. Select OTHER DEVICES from the HARDWARE TYPES list.
6. Click HAVE DISK.
7. Specify the location of the driver files and click OK.
8. Select the file S1D13XXX.INF and click OK.
9. Click OK.
10. The EPSON PCI Bridge Card should be selected in the list window.
11. Click NEXT.
12. Click NEXT.
13. Click Finish.

1 Introduction

This manual describes the setup and operation of the S5U13506B00C Evaluation Board. The S5U13506B00C is designed as an evaluation platform for the S1D13506 Color LCD/CRT/TV Controller chip.

This user manual will be updated as appropriate. Please check the Epson Research and Development Website at http://www.erd.epson.com for the latest revision of this document before beginning any development.

We appreciate your comments on our documentation. Please contact us via email at documentation@erd.epson.com.
2 Features

The S5U13506B00C features the following:

- S1D13506 Color LCD/CRT/TV controller chip.
- Headers for connecting to a 3.3V or 5V host bus interface.
- 1Mx16 EDO DRAM.
- Configuration options.
- Adjustable positive LCD bias power supplies from +24V to +40V.
- Adjustable negative LCD bias power supplies from -23V to -14V.
- 4/8-bit 3.3V or 5V monochrome passive LCD panel support.
- 4/8/16-bit 3.3V or 5V color passive LCD panel support.
- 9/12/18-bit 3.3V or 5V TFT/D-TFD LCD panel support.
- Embedded RAMDAC for CRT and TV support.
- WINNOV VideumCam digital camera support at 320x240x256 colors at 30 frames per second.
- Clock synthesizer for maximum clock flexibility.
- Software initiated Power Save Mode.
- Selectable clock source for BUSCLK and CLKI.
3 Installation and Configuration

The S5U13506B00C is designed to support as many platforms as possible. The S5U13506B00C incorporates a DIP switch and several jumpers which allow both evaluation board and S1D13506 LCD controller settings to be configured for a specified evaluation platform.

3.1 Configuration DIP Switches

The S1D13506 LCD controller has 16 configuration inputs (MD[15:0]) which are read on the rising edge of RESET#. Where appropriate, the S5U13506B00C hard-wires some of these configuration inputs, but in order to configure the S1D13506 for multiple host bus interfaces a ten-position DIP switch is required. The following DIP switch settings configure the S1D13506.

Table 3-1: Configuration DIP Switch Settings

= Default configuration
4 Technical Description

The S5U13506B00C operates with both PCI and non-PCI evaluation platforms. It supports display types such as, passive LCD panels (4/8/16-bit), TFT/D-TFD panels (9/12/18-bit), CRT and TV (NTSC and PAL). Additionally, it supports a variety of clock options.

4.1 PCI Bus Support

As a PCI device, the S5U13506B00C has the following characteristics.

- 33MHz bus clock.
- Target with no interrupts.
- Non-cacheable memory read and write.
- 3.3V or 5V PCI signalling.

Note
In a 3.3V PCI system, the S1D13506 must be powered at 3.3V by setting jumper JP1. In a 5V PCI system, the S1D13506 may be powered at either 3.3V or 5V.

Although the S1D13506 does not support the PCI bus directly, the S5U13506B00C supports the PCI bus using a PCI Bridge Adapter FPGA. The FPGA translates PCI accesses into PC Card accesses which are then decoded by the S1D13506.

A 4M byte PCI address range is allocated to the S5U13506B00C by the system BIOS. The S1D13506 uses this address range to map the internal registers and the 2M byte display buffer. The following table shows the memory mapping of the PCI address block.

Table 4-1: S1D13506 Memory Mapping onto 4M byte PCI Address Block

<table>
<thead>
<tr>
<th>PCI Memory Offset</th>
<th>Description</th>
<th>S1D13506 M/R#</th>

</tr>
</tbody>
</table>
4.1.1 On-Board PCI Configuration Registers

Read-Only Registers

The PCI Bridge Adapter FPGA provides configuration registers which contain identification information required by the PCI interface. The following values are hard-wired into these registers.

<table>
<thead>
<tr>
<th>Name</th>
<th>Address</th>
<th>Register size</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vendor ID</td>
<td>0h</td>
<td>16 bits</td>

</tr>
<tr>
<td>n/a</td>
<td>Fh-FFh</td>
<td>32 bits</td>
<td>0</td>
</tr>
</tbody>
</table>

Table 4-2: PCI Configuration Register Read Values

Read/Write Registers

The PCI Bridge Adapter FPGA provides two read/write registers which are used for access enabling and memory mapping as follows.

<table>
<thead>
<tr>
<th>Name</th>
<th>Address</th>
<th>Register size</th>
<th>Valid bits</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command</td>
<td>4h</td>
<td>16 bits</td>
<td>Bit 1 only; other bits are zero.</td>
<td>Access enabled if high</td>
</tr>
<tr>
<td>Base Address</td>
<td>10h</td>
<td>32 bits</td>
<td>Bits 31 to 22; other bits are zero.</td>
<td>Position of 4M byte reserved window</td>
</tr>
</tbody>
</table>

4.1.2 Utility Software

All utility software for the S5U13506B00C evaluation board is fully PCI compliant and handles the PCI configuration registers automatically.
4.2 Non-PCI Host Interface Support

The S5U13506B00C is specifically designed to support a standard PCI bus environment (using the PCI Bridge Adapter FPGA). However, the S5U13506B00C can directly support many other Host Bus Interfaces. When the FPGA is disabled (using jumper JP9), headers H1 and H2 provide the necessary IO pins to interface to the Host Bus Interfaces listed in Table 4-4; “CPU Interface Pin Mapping”. The S1D13506 power supply must be set to 3.3V or 5V (using jumper JP1) according to the host CPU signalling voltage.

4.2.1 CPU Interface Pin Mapping

The functions of the S1D13506 host interface pins are mapped to each host bus interface according to the following table.

<table>
<thead>
<tr>
<th>S1D1350 Pin Names</th>
<th>Generic</th>
<th>Hitachi SH-4/SH-3</th>

4.3 LCD Support

The S1D13506 supports 4/8-bit dual and single passive monochrome panels, 4/8/16-bit dual and single passive color panels, and 9/12/18-bit active matrix color TFT/D-TFD panels. All necessary signals are provided on the 40-pin LCD connector (J1). The interface signals are alternated with grounds on the cable to reduce cross-talk and noise. When supporting an 18-bit TFT/D-TFD panel, the S1D13506 can display 64K of a possible 256K colors because only 16 of the 18 bits of LCD data are available from the S1D13506. For details, refer to the *S1D13506 Hardware Functional Specification*, document number X25B-A-001-xx.

For S1D13506 FPDAT[15:0] pin mapping for various types of panel see Table 4-7; “LCD Signal Connector (J1)” on page 17.
# 4.3.1 LCD Interface Pin Mapping

**Note**

2. The S5U13506B00C was designed using S1D13506 pin 75 (LCDPWR) to control the LCD bias power. This design is **no longer supported**. Applications should use one of the available GPIO pins to control the LCD bias power allowing for software control of power sequencing delays. For further information on LCD power sequencing, see the *S1D13506 Programming Notes and Examples*, document number X25B-G-003-xx.
4.3.2 Buffered LCD Connector

J1 provides the same LCD panel signals as those directly from S1D13506, but with voltage-adapting buffers which can be set to 3.3V or 5V. Pin 32 on this connector provides power for the LCD panel logic at the same voltage as the buffer power supply.

4.3.3 16-bit Passive Color Panel Support with MediaPlug Enabled

When the MediaPlug option is enabled, (MD13 and MD14 set to “On”, see Table 3-1: “Configuration DIP Switch Settings” on page 9) S1D13506 pins FPDAT[15:8] are used for the MediaPlug interface and are not available for panel connection. Instead, S1D13506 pins FPDAT[7:0] are multiplexed for 16-bit panel operation. If the MediaPlug option is selected and 16-bit panel operation is desired, demultiplexing circuitry must be built externally according to the schematic below. Refer to Table 4-7: “LCD Signal Connector (J1)” on page 17 for connector pin mapping.

Single color 16-bit passive panels can be used with the following modifications.

![Figure 4-1: External Circuit for Color Single 16-Bit Panel with MediaPlug Enabled](image1)

Dual color 16-bit passive panels can be used with the following modifications.

![Figure 4-2: External Circuit for Color Dual 16-Bit Panel with MediaPlug Enabled](image2)
4.3.4 Adjustable LCD Panel Positive Power Supply

For LCD panels which require a positive bias voltage between +24V and +40V (Iout=45mA), a power supply has been provided as an integral part of the S5U13506B00C design. The voltage on VDDH can be adjusted using R15 to provide an output voltage from +24V to +40V and can be enabled and disabled by LCDPWR (S1D13506 pin 75).

The S5U13506B00C was designed using LCDPWR (pin 75) to control the LCD bias power. This design is no longer supported. Applications should use one of the available GPIO pins to control the LCD bias power allowing for software control of power sequencing delays. For further information on LCD power sequencing, see the S1D13506 Programming Notes and Examples, document number X25B-G-003-xx.

Note
Before connecting the panel, set the potentiometer according to the panel’s specific voltage requirements.

4.3.5 Adjustable LCD Panel Negative Power Supply

For LCD panels which require a negative bias voltage between -23V and -14V (Iout=25mA), a power supply has been provided as an integral part of the S5U13506B00C design. The voltage on VLCD can be adjusted using R21 to provide an output voltage from -23V to -14V, and can be enabled and disabled by LCDPWR (S1D13506 pin 75).

The S5U13506B00C was designed using LCDPWR (pin 75) to control the LCD bias power. This design is no longer supported. Applications should use one of the available GPIO pins to control the LCD bias power allowing for software control of power sequencing delays. For further information on LCD power sequencing, see the S1D13506 Programming Notes and Examples, document number X25B-G-003-xx.

Note
Before connecting the panel, set the potentiometer according to the panel’s specific voltage requirements.
4.4 CRT/TV Support

4.4.1 CRT/TV Interface Pin Mapping

CRT/TV signals are supplied on a standard CRT connector (J3), Composite Video connector (J2), and S-Video connector (J4):

<table>
<thead>
<tr>
<th>CRT/TV Interface Pin Mapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>S1D13506 Pin Name</td>
</tr>
<tr>
<td>HRTC</td>
</tr>
<tr>
<td>VRTC</td>
</tr>
<tr>
<td>RED</td>
</tr>
<tr>
<td>GREEN</td>
</tr>
<tr>
<td>BLUE</td>
</tr>
</tbody>
</table>

4.4.2 CRT Support

CRT support is provided on connector J3 via the S1D13506 embedded RAMDAC. An external current reference is implemented to provide the necessary RAMDAC output gain. The reference current (IREF) should be set to 4.6mA using jumper JP7.

**Note**
- When IREF is set to 4.6mA, the DAC Output Select bit (REG[05Bh] bit 3) must be set to 1.
- CRT output is not available when TV output is enabled.

4.4.3 TV Support

The S1D13506 supports PAL or NTSC TV output. Composite Video is available on connector J2 and S-Video is available on connector J4. An external current reference is implemented to provide the necessary RAMDAC output gain. The reference current should be set to 9.2mA using jumper JP7.

TV output is not available when CRT output is enabled. PAL and NTSC modes cannot be enabled at the same time.
4.5 MediaPlug Interface

The S5U13506B00C supports the Winnov Videum® Cam digital camera through the S1D13506 built-in MediaPlug interface. The Winnov Videum® Cam digital camera inputs are TTL compatible and can be driven by the S1D13506 powered at 3.3V or 5V. Therefore, the power supply to the camera is 5V while the S1D13506 can powered at 3.3V or 5V. However, if the S1D13506 is powered at 5V, then 150nH inductors must be added at locations L8, L10, L11, L12 and L13.

Jumper JP5 selects whether MA11/GPIO2 is used to enable the video camera power. For more information, see the note from Section 3.2, “Configuration Jumpers” on page 10. Eight jumpers identified globally as JP3 must be set for MediaPlug operation.

The table below describes the S1D13506 pin mapping for the MediaPlug interface.

<table>
<thead>

</tbody>
</table>

Note
When MediaPlug is enabled, 16-bit passive panels support requires an external circuit. See Section 4.3.3, “16-bit Passive Color Panel Support with MediaPlug Enabled” on page 18.
4.6 Clock Synthesizer and Clock Options

For maximum flexibility, the S5U13506B00C implements a Cypress ICD2061A Clock Generator. MCLKOUT from the clock chip is connected to CLKI of the S1D13506 and VCLKOUT from the clock chip is connected to CLKI2 of the S1D13506. A 14.31818MHz crystal (Y1) is connected to XTALIN of the clock chip and a 17.734475MHz oscillator (U14) is connected to the FEATCLK input of the clock chip. The diagram below shows a simplified representation of the clock synthesizer connections.

![Figure 4-3: Symbolic Clock Synthesizer Connections](image)

Upon power-up, CLKI (MCLKOUT) is 40MHz and CLKI2 (VCLKOUT) is configured to 25.175MHz.

4.6.1 Clock Programming

The S1D13506 utilities automatically program the clock generator. If manual programming of the clock generator is required, refer to the source code for the S1D13506 utilities available on the internet at www.eea.epson.com.

For further information on programming the clock generator, refer to the Cypress ICD2061A specification.

**Note**

When CLKI and CLKI2 are programmed to multiples of each other (e.g. CLKI = 20MHz, CLKI2 = 40MHz), the clock output signals from the Cypress clock generator may jitter. Refer to the Cypress ICD2061A specification for details.

To avoid this problem, set CLKI and CLKI2 to different frequencies and configure both LCD PCLK and CRT/TV PCLK to use the same clock input (CLKI or CLKI2). Then use the S1D13506 internal clock divides (LCD PCLK Divide Select REG[014h] bits 5-4, CRT/TV PCLK Divide Select REG[018h] bits 5-4) to obtain the lower frequencies.

1 Introduction

This application note describes the hardware and software environment required to provide an interface between the S1D13506 Color LCD/CRT/TV Controller and the PC Card (PCMCIA) bus.

The designs described in this document are presented only as examples of how such interfaces might be implemented. This application note will be updated as appropriate. Please check the Epson Electronics America website at http://www.eea.epson.com for the latest revision of this document before beginning any development.

We appreciate your comments on our documentation. Please contact us via email at documentation@erd.epson.com.
2 Interfacing to the PC Card Bus

2.1 The PC Card System Bus

PC Card technology has gained wide acceptance in the mobile computing field as well as in other markets due to its portability and ruggedness. This section is an overview of the operation of the 16-bit PC Card interface conforming to the PCMCIA 2.0/JEIDA 4.1 Standard (or later).

2.1.1 PC Card Overview

The 16-bit PC Card provides a 26-bit address bus and additional control lines which allow access to three 64M byte address ranges. These ranges are used for common memory space, IO space, and attribute memory space. Common memory may be accessed by a host system for memory read and write operations. Attribute memory is used for defining card specific information such as configuration registers, card capabilities, and card use. IO space maintains software and hardware compatibility with hosts such as the Intel x86 architecture, which address peripherals independently from memory space.

Bit notation follows the convention used by most micro-processors, the high bit being the most significant. Therefore, signals A25 and D15 are the most significant bits for the address and data busses respectively.

Support is provided for on-chip DMA controllers. To find further information on these topics, refer to Section 6, “References” on page 18.

PC Card bus signals are asynchronous to the host CPU bus signals. Bus cycles are started with the assertion of the CE1# and/or the CE2# card enable signals. The cycle ends once these signals are de-asserted. Bus cycles can be lengthened using the WAIT# signal.

Note
The PCMCIA 2.0/JEIDA 4.1 (and later) PC Card Standard support the two signals WAIT# and RESET which are not supported in earlier versions of the standard. The WAIT# signal allows for asynchronous data transfers for memory, attribute, and IO access cycles. The RESET signal allows resetting of the card configuration by the reset line of the host CPU.

2.1.2 Memory Access Cycles

A data transfer is initiated when a memory address is placed on the PC Card bus and one, or both, of the card enable signals (CE1# and CE2#) are driven low. REG# must be inactive. If only CE1# is driven low, 8-bit data transfers are enabled and A0 specifies whether the even or odd data byte appears on data bus lines D[7:0]. If both CE1# and CE2# are driven low, a 16-bit word transfer takes place. If only CE2# is driven low, an odd byte transfer occurs on data lines D[15:8].
During a read cycle, OE# (output enable) is driven low. A write cycle is specified by driving OE# high and driving the write enable signal (WE#) low. The cycle can be lengthened by driving WAIT# low for the time needed to complete the cycle.

Figure 2-1: illustrates a typical memory access read cycle on the PC Card bus.
Figure 2-2: illustrates a typical memory access write cycle on the PC Card bus.

Figure 2-2: PC Card Write Cycle
3 S1D13506 Host Bus Interface

The S1D13506 implements a 16-bit PC Card (PCMCIA) Host Bus Interface which is used to interface to the PC Card bus.

The PC Card Host Bus Interface is selected by the S1D13506 on the rising edge of RESET#. After releasing reset the bus interface signals assume their selected configuration. For details on S1D13506 configuration, see Section 4.2, “S1D13506 Hardware Configuration” on page 15.

Note

At reset, the Register/Memory Select bit in the Miscellaneous Register (REG[001h] bit 7) is set to 1. This means that only REG[000h] (read-only) and REG[001h] are accessible until a write to REG[001h] sets bit 7 to 0 making all registers accessible. When debugging a new hardware design, this can sometimes give the appearance that the interface is not working, so it is important to remember to clear this bit before proceeding with debugging.

3.1 PC Card Host Bus Interface Pin Mapping

The following table shows the functions of each Host Bus Interface signal.

</tr>
</tbody>
</table>

Note

¹The bus signal A0 is not used by the S1D13506 internally.

²Although a clock is not directly supplied by the PC Card interface, one is required by the S1D13506 PC Card Host Bus Interface. For an example of how this can be accomplished see the discussion on BUSCLK in Section 3.2, “PC Card Host Bus Interface Signals” on page 12.
3.2 PC Card Host Bus Interface Signals

The S1D13506 PC Card Host Bus Interface is designed to support processors which interface the S1D13506 through the PC Card bus.

The S1D13506 PC Card Host Bus Interface requires the following signals from the PC Card bus.

- **BUSCLK**: a clock input which is required by the S1D13506 Host Bus Interface. It is separate from the input clock (CLKI) and is typically driven by the host CPU system clock. Since PC Card signalling is independent of any clock, BUSCLK can come from any oscillator already implemented. For example, the source for the CLKI input of the S1D13506 may be used.

- The address inputs AB[20:1] and the data bus DB[15:0] connect directly to the PC Card address (A[20:1]) and data bus (D[15:0]), respectively. MD4 must be set to select little endian mode upon reset.

- **M/R# (memory/register)** selects between memory or register access. It may be connected to an address line, allowing system address A21 to be connected to the M/R# line.

- **Chip Select (CS#)** must be driven low whenever the S1D13506 is accessed by the PC Card bus.

- **WE1# and RD/WR#** connect to CE2# and CE1# (the byte enables for the high-order and low-order bytes). They are driven low when the PC Card bus is accessing the S1D13506.

- **RD#** connects to OE# (the read enable signal from the PC Card bus).

- **WE0#** connects to WE# (the write enable signal from the PC Card bus).

- **WAIT#** is a signal output from the S1D13506 that indicates the PC Card bus must wait until data is ready (read cycle) or accepted (write cycle) on the host bus. Since PC Card bus accesses to the S1D13506 may occur asynchronously to the display update, it is possible that contention may occur in accessing the S1D13506 internal registers and/or display buffer. The WAIT# line resolves these contentions by forcing the host to wait until the resource arbitration is complete. For PC Card applications, this signal should be set active low using the MD5 configuration input.

- The **Bus Start (BS#)** signal is not used for the PC Card Host Bus Interface and should be tied high (connected to VDD).

- The **RESET# (active low)** input of the S1D13506 may be connected to the PC Card RESET (active high) using an inverter.
4 PC Card to S1D13506 Interface

4.1 Hardware Description

The S1D13506 is designed to directly support a variety of CPUs, providing an interface to each processor’s unique “local bus”. However, in order to provide support for processors not having an appropriate local bus, the S1D13506 supports a specific PC Card interface.

The S1D13506 provides a “glueless” interface to the PC Card bus except for the following.

- The RESET# signal on the S1D13506 is active low and must be inverted to support the active high RESET provided by the PC Card interface.
- Although the S1D13506 supports an asynchronous bus interface, a clock source is required on the BUSCLK input pin.

In this implementation, the address inputs (AB[20:1]) and data bus (DB[15:0]) connect directly to the CPU address (A[20:1]) and data bus (D[15:0]). M/R# is treated as an address line so that it can be controlled using system address A21.

The PC Card interface does not provide a bus clock, so one must be supplied for the S1D13506. Since the bus clock frequency is not critical, nor does it have to be synchronous to the bus signals, it may be the same as CLKI. BS# (bus start) is not used and should be tied high (connected to \( V_{DD} \)).
The following shows a typical implementation of the PC Card to S1D13506 interface.

Note:
When connecting the S1D13506 RESET# pin, the system designer should be aware of all conditions that may reset the S1D13506 (e.g. CPU reset can be asserted during wake-up from power-down modes, or during debug states).

*Figure 4-1: Typical Implementation of PC Card to S1D13506 Interface*
4.2 S1D13506 Hardware Configuration

The S1D13506 latches MD15 through MD0 to allow selection of the bus mode and other configuration data on the rising edge of RESET#. For details on configuration, refer to the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx.

The table below shows only those configuration settings important to the PC Card Host Bus Interface.

*Table 4-1: Summary of Power-On/Reset Options*

<table>
<thead>
<tr>
<th>S1D13506 Pin Name</th>

<tr>
<td>MD15</td>
<td>WAIT# is always driven</td>
</tr>
</tbody>
</table>

= configuration for PC Card Host Bus Interface

4.3 Performance

The S1D13506 PC Card Interface specification supports a BCLK up to 50MHz, and therefore can provide a high performance display solution.
4.4 Register/Memory Mapping

The S1D13506 is a memory mapped device. The internal registers require 47 bytes and are mapped in the lower PC Card memory address space starting at zero. The display buffer requires 2M bytes and is mapped in the third and fourth megabytes of the PC Card address space (ranging from 200000h to 3FFFFFFh).

A typical implementation as shown in Figure 4-1: “Typical Implementation of PC Card to S1D13506 Interface,” on page 14 has Chip Select (CS#) connected to ground (always enabled) and the Memory/Register select pin (M/R#) connected to address bit A21. This provides the following decoding:

Table 4-2: Register/Memory Mapping for Typical Implementation

<table>
<thead>
<tr>
<th>CS#</th>
<th>M/R# (A21)</th>
<th>Address Range</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0 - 1FFFFh</td>
<td>Internal Register set decoded</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>200000h - 3FFFFh</td>
<td>Display Buffer decode</td>
</tr>
</tbody>
</table>

The PC Card socket provides 64M byte of address space. Without further resolution on the decoding logic (M/R# connected to A21), the entire register set is aliased for every 64 byte boundary within the specified address range above. Since address bits A[25:22] are ignored, the S1D13506 registers and display buffer are aliased 16 times.

Note

If aliasing is not desirable, the upper addresses must be fully decoded.
5 Software

Test utilities and Windows® CE display drivers are available for the S1D13506. Full source code is available for both the test utilities and the drivers.

The test utilities are configurable for different panel types using a program called 13506CFG, or by directly modifying the source. The Windows CE display drivers can be customized by the OEM for different panel types, resolutions and color depths only by modifying the source.

The S1D13506 test utilities and Windows CE display drivers are available from your sales support contact or on the internet at http://www.eea.epson.com.

S1D13506 Color LCD/CRT/TV Controller

Power Consumption

Document Number: X25B-G-006-02
THIS PAGE LEFT BLANK
1 S1D13506 Power Consumption

S1D13506 power consumption is affected by many system design variables.

- Input clock frequency (CLKI/CLKI2): the CLKI/CLKI2 frequency determines the LCD/CRT frame-rate, CPU performance to memory, and other functions – the higher the input clock frequency, the higher the frame-rate, performance and power consumption.

- CPU interface: the S1D13506 current consumption depends on the BUSCLK frequency, data width, number of toggling pins, and other factors – the higher the BUSCLK, the higher the CPU performance and power consumption.

- VDD voltage level: the voltage level affects power consumption – the higher the voltage, the higher the consumption.

- Display mode: the resolution and color depth affect power consumption – the higher the resolution/color depth, the higher the consumption.

- Internal CLK divide: internal registers allow the input clock to be divided before going to the internal logic blocks – the higher the divide, the lower the power consumption.

There is a power save mode in the S1D13506. The power consumption is affected by various system design variables.

- DRAM refresh mode (CBR or self-refresh): self-refresh capable DRAM allows the S1D13506 to disable the internal memory clock thereby saving power.

- Clock states during the power save mode: disabling the clocks during power save mode has substantial power savings.
1.1 Conditions

**Note**

1. Conditions for software suspend with Clocks active:
   - CPU interface inactive
   - CLKI, CLKI2, BUSCLK active
   - Self-Refresh DRAM
2. Conditions for software suspend with Clocks inactive:
   - CPU interface inactive
   - CLKI, CLKI2, BUSCLK stopped
   - Self-Refresh DRAM
Summary

The system design variables in Section 1, “S1D13506 Power Consumption” and in Table 1-1: “S1D13506 Power Consumption” show that S1D13506 power consumption depends on the specific implementation. Active Mode power consumption depends on the desired CPU performance and LCD/CRT frame-rate, whereas power save mode consumption depends on the CPU Interface and Input Clock state.

In a typical design environment, the S1D13506 can be configured to be an extremely power-efficient LCD/CRT/TV Controller with high performance and flexibility.

1 Introduction

This application note describes the hardware and software environment necessary to provide an interface between the S1D13506 Color LCD/CRT/TV Controller and the NEC VR4102™ (μPD30102) or VR4111™ (μPD30111) Microprocessors.

The designs described in this document are presented only as examples of how such interfaces might be implemented. This application note will be updated as appropriate. Please check the Epson Electronics America Website at http://www.eea.epson.com for the latest revision of this document before beginning any development.

We appreciate your comments on our documentation. Please contact us via email at techpubs@erd.epson.com.
2 Interfacing to the VR4102/VR4111

2.1 The NEC VR4102/VR4111 System Bus

The VR-Series family of microprocessors features a high-speed synchronous system bus typical of modern microprocessors. Designed with external LCD controller support and Windows CE based embedded consumer applications in mind, the VR4102/VR4111 offers a highly integrated solution for portable systems. This section provides an overview of the operation of the CPU bus in order to establish interface requirements.

2.1.1 Overview

The NEC VR4102/VR4111 is designed around the RISC architecture developed by MIPS. This microprocessor is based on the 66MHz VR4100 CPU core which supports 64-bit processing. The CPU communicates with the Bus Control Unit (BCU) using its internal SysAD bus. The BCU in turn communicates with external devices using its ADD and DAT buses which can be dynamically sized for 16 or 32-bit operation.

The NEC VR4102/VR4111 has direct support for an external LCD controller. Specific control signals are assigned for an external LCD controller providing an easy interface to the CPU. A 16M byte block of memory is assigned for the LCD controller and its own chip select and ready signals are available. Word or byte accesses are controlled by the system high byte signal (SHB#).
2.1.2 LCD Memory Access Cycles

Once an address in the LCD block of memory is placed on the external address bus (ADD[25:0]), the LCD chip select (LCDCS#) is driven low. The read or write enable signals (RD# or WR#) are driven low for the appropriate cycle and LCDRDY is driven low to insert wait states into the cycle. The high byte enable (SHB#) in conjunction with address bit 0 allows for byte steering.

The following figure illustrates typical NEC VR4102/VR4111 memory read and write cycles to the LCD controller interface.

![Figure 2-1: NEC VR4102/VR4111 Read/Write Cycles](image)
3 S1D13506 Host Bus Interface

The S1D13506 directly supports multiple processors. The S1D13506 implements a 16-bit MIPS/ISA Host Bus Interface which is most suitable for direct connection to the VR4102/VR4111 microprocessor.

The MIPS/ISA Host Bus Interface is selected by the S1D13506 on the rising edge of RESET#. After releasing reset the bus interface signals assume their selected configuration. For details on S1D13506 configuration, see Section 4.2, “S1D13506 Hardware Configuration” on page 13.

Note
At reset, the Register/Memory Select bit in the Miscellaneous Register (REG[001h] bit 7) is set to 1. This means that only REG[000h] (read-only) and REG[001h] are accessible until a write to REG[001h] sets bit 7 to 0 making all registers accessible. When debugging a new hardware design, this can sometimes give the appearance that the interface is not working, so it is important to remember to clear this bit before proceeding with debugging.

3.2 Host Bus Interface Signal Descriptions

The S1D13506 MIPS/ISA Host Bus Interface requires the following signals.

- **BUSCLK** is a clock input which is required by the S1D13506 Host Bus Interface. It is separate from the input clock (CLKI) and is typically driven by the host CPU system clock.

- The address inputs AB[20:0], and the data bus DB[15:0], connect directly to the VR4102/VR4111 address (ADD[20:0]) and data bus (DAT[15:0]), respectively. MD4 must be set to select the proper endian mode upon reset.

- **M/R#** (memory/register) selects between memory or register access. It may be connected to an address line, allowing system address ADD21 to be connected to the M/R# line.

- Chip Select (CS#) must be driven low by LCDCS# whenever the S1D13506 is accessed by the VR4102/VR4111.

- **WE1#** connects to SHB# (the high byte enable signal from the VR4102/VR4111) which in conjunction with address bit 0 allows byte steering of read and write operations.

- **WE0#** connects to WR# (the write enable signal from the VR4102/VR4111) and must be driven low when the VR4102/VR4111 is writing data to the S1D13506.

- **RD#** connects to RD# (the read enable signal from the VR4102/VR4111) and must be driven low when the VR4102/VR4111 is reading data from the S1D13506.

- **WAIT#** connects to LCDRDY and is a signal output from the S1D13506 that indicates the VR4102/VR4111 must wait until data is ready (read cycle) or accepted (write cycle) on the host bus. Since VR4102/VR4111 accesses to the S1D13506 may occur asynchronously to the display update, it is possible that contention may occur in accessing the S1D13506 internal registers and/or display buffer. The WAIT# line resolves these contentions by forcing the host to wait until the resource arbitration is complete.

- The BS# and RD/WR# signals are not used for the MIPS/ISA Host Bus Interface and should be tied high (connected to VDD).
4 VR4102/VR4111 to S1D13506 Interface

4.1 Hardware Description

The NEC VR4102/VR4111 Microprocessors are specifically designed to support an external LCD controller. They provide the necessary internal address decoding and control signals.

The diagram below shows a typical implementation utilizing the S1D13506.

Note:
When connecting the S1D13506 RESET# pin, the system designer should be aware of all conditions that may reset the S1D13506 (e.g., CPU reset can be asserted during wake-up from power-down modes, or during debug states).

Figure 4-1: NEC VR4102/VR4111 to S1D13506 Configuration Schematic

Note
For pin mapping see Table 3-1, “Host Bus Interface Pin Mapping,” on page 10.
4.2 S1D13506 Hardware Configuration

The S1D13506 latches MD15 through MD0 to allow selection of the bus mode and other configuration data on the rising edge of RESET#. For details on configuration, refer to the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx.

The table below shows those configuration settings important to the NEC VR4102/VR4111 CPU interface.

= configuration for NEC VR4102/VR4111 microprocessor

4.3 NEC VR4102/VR4111 Configuration

NEC VR4102/VR4111 The NEC VR4102/VR4111 provides the internal address decoding necessary to map an external LCD controller. Physical address 0A00 0000h to 0AFF FFFFh (16M bytes) is reserved for an external LCD controller.

The S1D13506 supports up to 2M bytes of display buffer. The NEC VR4102/VR4111 address line A21 is used to select between the S1D13506 display buffer (A21=1) and internal registers (A21=0).

The NEC VR4102/VR4111 has a 16-bit internal register named BCUCNTREG2 located at address 0B00 0002h. It must be set to the value of 0001h to indicate that LCD controller accesses using a non-inverting data bus.
5 Software

Test utilities and Windows® CE v2.0 display drivers are available for the S1D13506. Full source code is available for both the test utilities and the drivers.

The test utilities are configurable for different panel types using a program called 13506CFG, or by directly modifying the source. The Windows CE v2.0 display drivers can be customized by the OEM for different panel types, resolutions and color depths only by modifying the source.

The S1D13506 test utilities and Windows CE v2.0 display drivers are available from your sales support contact or on the internet at http://www.eea.epson.com.

1 Introduction

This application note describes the hardware and software environment required to provide an interface between the S1D13506 Color LCD/CRT/TV Controller and the Motorola MPC821 processor.

The designs described in this document are presented only as examples of how such interfaces might be implemented. This application note will be updated as appropriate. Please check the Epson Electronics America Website at http://www.eea.epson.com for the latest revision of this document before beginning any development.

We appreciate your comments on our documentation. Please contact us via email at documentation@erd.epson.com.
2 Interfacing to the MPC821

2.1 The MPC8xx System Bus

The MPC8xx family of processors feature a high-speed synchronous system bus typical of modern RISC microprocessors. This section provides an overview of the operation of the CPU bus in order to establish interface requirements.

2.2 MPC821 Bus Overview

The MPC8xx microprocessor family uses a synchronous address and data bus. All IO is synchronous to a square-wave reference clock called MCLK (Master Clock). This clock runs at the machine cycle speed of the CPU core (typically 25 to 50 MHz). Most outputs from the processor change state on the rising edge of this clock. Similarly, most inputs to the processor are sampled on the rising edge.

**Note**
The external bus can run at one-half the CPU core speed using the clock control register. This is typically used when the CPU core is operated above 50 MHz.

The MPC821 can generate up to eight independent chip select outputs, each of which may be controlled by one of two types of timing generators: the General Purpose Chip Select Module (GPCM) or the User-Programmable Machine (UPM). Examples are given using the GPCM.

It should be noted that all Power PC microprocessors, including the MPC8xx family, use bit notation opposite from the convention used by most other microprocessor systems. Bit numbering for the MPC8xx always starts with zero as the most significant bit, and increments in value to the least-significant bit. For example, the most significant bits of the address bus and data bus are A0 and D0, while the least significant bits are A31 and D31.

The MPC8xx uses both a 32-bit address and data bus. A parity bit is supported for each of the four byte lanes on the data bus. Parity checking is done when data is read from external memory or peripherals, and generated by the MPC8xx bus controller on write cycles. All IO accesses are memory-mapped meaning there is no separate IO space in the Power PC architecture.

Support is provided for both on-chip (DMA controllers) and off-chip (other processors and peripheral controllers) bus masters. For further information on this topic, refer to Section 6, “References” on page 22.

The bus can support both normal and burst cycles. Burst memory cycles are used to fill on-chip cache memory, and for certain on-chip DMA operations. Normal cycles are used for all other data transfers.
2.2.1 Normal (Non-Burst) Bus Transactions

A data transfer is initiated by the bus master by placing the memory address on address lines A0 through A31 and driving $\overline{TS}$ (Transfer Start) low for one clock cycle. Several control signals are also provided with the memory address:

- TSIZ[0:1] (Transfer Size) -- indicates whether the bus cycle is 8, 16, or 32-bit.
- RD/WR -- set high for read cycles and low for write cycles.
- AT[0:3] (Address Type Signals) -- provides more detail on the type of transfer being attempted.

When the peripheral device being accessed has completed the bus transfer, it asserts $\overline{TA}$ (Transfer Acknowledge) for one clock cycle to complete the bus transaction. Once $\overline{TA}$ has been asserted, the MPC821 will not start another bus cycle until $\overline{TA}$ has been de-asserted. The minimum length of a bus transaction is two bus clocks.

Figure 2-1: “Power PC Memory Read Cycle” on page 9 illustrates a typical memory read cycle on the Power PC system bus.

![Figure 2-1: Power PC Memory Read Cycle](image-url)
Figure 2-2: “Power PC Memory Write Cycle” on page 10 illustrates a typical memory write cycle on the Power PC system bus.

If an error occurs, TEA (Transfer Error Acknowledge) is asserted and the bus cycle is aborted. For example, a peripheral device may assert TEA if a parity error is detected, or the MPC821 bus controller may assert TEA if no peripheral device responds at the addressed memory location within a bus time-out period.

For 32-bit transfers, all data lines (D[0:31]) are used and the two low-order address lines A30 and A31 are ignored. For 16-bit transfers, data lines D[0:15] are used and address line A31 is ignored. For 8-bit transfers, data lines D[0:7] are used and all address lines (A[0:31]) are used.

Note
This assumes that the Power PC core is operating in big endian mode (typically the case for embedded systems).

2.2.2 Burst Cycles

Burst memory cycles are used to fill on-chip cache memory and to carry out certain on-chip DMA operations. They are very similar to normal bus cycles with the following exceptions:

- Always 32-bit.
- Always attempt to transfer four 32-bit words sequentially.
- Always address longword-aligned memory (i.e. A30 and A31 are always 0:0).
- Do not increment address bits A28 and A29 between successive transfers; the addressed device must increment these address bits internally.
If a peripheral is not capable of supporting burst cycles, it can assert Burst Inhibit (BI) simultaneously with TA, and the processor will revert to normal bus cycles for the remaining data transfers.

Burst cycles are mainly intended to facilitate cache line fills from program or data memory. They are normally not used for transfers to/from IO peripheral devices such as the S1D13506, therefore the interfaces described in this document do not attempt to support burst cycles. However, the example interfaces include circuitry to detect the assertion of BDIP and respond with BI if caching is accidently enabled for the S1D13506 address space.

### 2.3 Memory Controller Module

#### 2.3.1 General-Purpose Chip Select Module (GPCM)

The General-Purpose Chip Select Module (GPCM) is used to control memory and peripheral devices which do not require special timing or address multiplexing. In addition to the chip select output, it can generate active-low Output Enable (OE) and Write Enable (WE) signals compatible with most memory and x86-style peripherals. The MPC821 bus controller also provides a Read/Write (RD/WR) signal which is compatible with most 68K peripherals.

The GPCM is controlled by the values programmed into the Base Register (BR) and Option Register (OR) of the respective chip select. The Option Register sets the base address, the block size of the chip select, and controls the following timing parameters:

- The ACS bit field allows the chip select assertion to be delayed by 0, ¼, or ½ clock cycle with respect to the address bus valid.
- The CSNT bit causes chip select and WE to be negated ½ clock cycle earlier than normal.
- The TRLX (relaxed timing) bit will insert an additional one clock delay between assertion of the address bus and chip select. This accommodates memory and peripherals with long setup times.
- The EHTR (Extended hold time) bit will insert an additional 1 clock delay on the first access to a chip select.
- Up to 15 wait states may be inserted, or the peripheral can terminate the bus cycle itself by asserting TA (Transfer Acknowledge).
- Any chip select may be programmed to assert BI (Burst Inhibit) automatically when its memory space is addressed by the processor core.
2.3.2 User-Programmable Machine (UPM)

The UPM is typically used to control memory types, such as Dynamic RAMs, which have complex control or address multiplexing requirements. The UPM is a general purpose RAM-based pattern generator which can control address multiplexing, wait state generation, and five general-purpose output lines on the MPC821. Up to 64 pattern locations are available, each 32 bits wide. Separate patterns may be programmed for normal accesses, burst accesses, refresh (timer) events, and exception conditions. This flexibility allows almost any type of memory or peripheral device to be accommodated by the MPC821.

In this application note, the GPCM is used instead of the UPM, since the GPCM has enough flexibility to accommodate the S1D13506 and it is desirable to leave the UPM free to handle other interfacing duties, such as EDO DRAM.
3 S1D13506 Host Bus Interface

The S1D13506 implements a 16-bit native PowerPC host bus interface which is used to interface to the MPC821 microprocessor.

The PowerPC host bus interface is selected by the S1D13506 on the rising edge of RESET#. After releasing reset the bus interface signals assume their selected configuration. For details on S1D13506 configuration, see Section 4.3, “S1D13506 Hardware Configuration” on page 18.

**Note**
At reset, the Register/Memory Select bit in the Miscellaneous Register (REG[001h] bit 7) is set to 1. This means that only REG[000h] (read-only) and REG[001h] are accessible until a write to REG[001h] sets bit 7 to 0 making all registers accessible. When debugging a new hardware design, this can sometimes give the appearance that the interface is not working, so it is important to remember to clear this bit before proceeding with debugging.

3.2 PowerPC Host Bus Interface Signals

The S1D13506 PowerPC host bus interface is designed to support processors which interface the S1D13506 through the PowerPC bus.

The S1D13506 PowerPC host bus interface requires the following signals:

- BUSCLK is a clock input which is required by the S1D13506 host bus interface. It is separate from the input clock (CLKI) and is typically driven by the host CPU system clock.

- The address inputs AB[20:0], and the data bus DB[15:0], connect directly to the PowerPC bus address (A[11:31]) and data bus (D[0:15]), respectively. MD4 must be set to select the proper endian mode upon reset.

- M/R# (memory/register) selects between memory or register access. It may be connected to an address line, allowing system address A10 to be connected to the M/R# line.

- Chip Select (CS#) must be driven low whenever the S1D13506 is accessed by the PowerPC bus.

- RD/WR# connects to RD/WR which indicates whether a read or a write access is being performed on the S1D13506.

- WE1# connects to BI (burst inhibit signal). WE1# is output by the S1D13506 to indicate whether the S1D13506 is able to perform burst accesses.

- WE0# and RD# connect to TSIZ1 and TSIZ0 (high and low byte enable signals). These signals must be driven by the PowerPC bus to indicate the size of the transfer taking place on the bus.

- WAIT# connects to TA and is output from the S1D13506 to indicate the PowerPC bus must wait until data is ready (read cycle) or accepted (write cycle) on the host bus. Since PowerPC bus accesses to the S1D13506 may occur asynchronously to the display update, it is possible that contention may occur while accessing the S1D13506 internal registers and/or display buffer. The WAIT# line resolves these contentions by forcing the host to wait until resource arbitration is complete.

- The Bus Start (BS#) signal connects to TS (the transfer start signal).
4  MPC821 to S1D13506 Interface

4.1 Hardware Description

The S1D13506 provides native Power PC bus support, making it very simple to interface the two devices. This application note describes the environment necessary to connect the S1D13506 to the MPC821 native system bus and the connections between the S5U13506B00B Evaluation Board and the Motorola MPC821 Application Development System (ADS).

The S1D13506, by implementing a dedicated display buffer, can reduce system power consumption, improve image quality, and increase system performance as compared to the MPC821’s on-chip LCD controller.

The S1D13506, through the use of the MPC821 chip selects, can share the system bus with all other MPC821 peripherals. The following figure demonstrates a typical implementation of the S1D13506 to MPC821 interface.

Note: When connecting the S1D13506 RESET# pin, the system designer should be aware of all conditions that may reset the S1D13506 (e.g., CPU reset can be asserted during wake-up from power-down modes, or during debug states).

Figure 4-1: Typical Implementation of MPC821 to S1D13506 Interface
Table 4-1: “List of Connections from MPC821ADS to S1D13506” on page 16 shows the connections between the pins and signals of the MPC821 and the S1D13506.

Note
The interface was designed using a Motorola MPC821 Application Development System (ADS). The ADS board has 5 volt logic connected to the data bus, so the interface included two 74F245 octal buffers on D[0:15] between the ADS and the S1D13506. In a true 3 volt system, no buffering is necessary.

4.2 Hardware Connections

The following table details the connections between the pins and signals of the MPC821 and the S1D13506.

**Note**

Note that the bit numbering of the Power PC bus signals is reversed. e.g. the most significant address bit is A0, the next is A1, A2, etc.
4.3 S1D13506 Hardware Configuration

The S1D13506 latches MD15 through MD0 to allow selection of the bus mode and other configuration data on the rising edge of RESET#. For details on configuration, refer to the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx.

The following table shows those configuration settings important to the MPC821 host bus interface.

<table>

</tbody>
</table>

= required settings for MPC821 support.

4.4 Register/Memory Mapping

The DRAM on the MPC821 ADS board extends from address 0 through 3F FFFFh, so the S1D13506 is addressed starting at 40 0000h. A total of 4M bytes of address space is used, where the lower 2M bytes is reserved for the S1D13506 on-chip registers and the upper 2M bytes is used to access the S1D13506 display buffer.
4.5 MPC821 Chip Select Configuration

Chip select 4 is used to control the S1D13506. The following options are selected in the base address register (BR4):

- \( \text{BA}[0:16] = 0000\ 0000\ 0100\ 0000\ 0 \) – set starting address of S1D13506 to 40 0000h.
- \( \text{AT}[0:2] = 0 \) – ignore address type bits.
- \( \text{PS}[0:1] = 1:0 \) – memory port size is 16-bit.
- \( \text{PARE} = 0 \) – disable parity checking.
- \( \text{WP} = 0 \) – disable write protect.
- \( \text{MS}[0:1] = 0:0 \) – select General Purpose Chip Select module to control this chip select.
- \( \text{V} = 1 \) – set valid bit to enable chip select.

The following options were selected in the option register (OR4):

- \( \text{AM}[0:16] = 1111\ 1111\ 1100\ 0000\ 0 \) – mask all but upper 10 address bits; S1D13506 consumes 4M byte of address space.
- \( \text{ATM}[0:2] = 0 \) – ignore address type bits.
- \( \text{CSNT} = 0 \) – normal \( \overline{CS}/\overline{WE} \) negation.
- \( \text{ACS}[0:1] = 1:1 \) – delay \( \overline{CS} \) assertion by \( \frac{1}{2} \) clock cycle from address lines.
- \( \text{BI} = 0 \) – do not assert Burst Inhibit.
- \( \text{SCY}[0:3] = 0 \) – wait state selection; this field is ignored since external transfer acknowledge is used; see SETA below.
- \( \text{SETA} = 1 \) – the S1D13506 generates an external transfer acknowledge using the \( \text{WAIT#} \) line.
- \( \text{TRLX} = 0 \) – normal timing.
- \( \text{EHTR} = 0 \) – normal timing.
4.6 Test Software

The test software is very simple. It configures chip select 4 (CS4) on the MPC821 to map the S1D13506 to an unused 4M byte block of address space. Next, it loads the appropriate values into the option register for CS4 and writes the value 0 to the S1D13506 register REG[001h] to enable full S1D13506 memory/register decoding. Lastly, the software runs a tight loop that reads the S1D13506 Revision Code Register REG[000h]. This allows monitoring of the bus timing on a logic analyzer.

The following source code was entered into the memory of the MPC821ADS using the line-by-line assembler in MPC8BUG (the debugger provided with the ADS board). Once the program was executed on the ADS, a logic analyzer was used to verify operation of the interface hardware.

It is important to note that when the MPC821 comes out of reset, the on-chip caches and MMU are disabled. If the data cache is enabled, then the MMU must be set so that the S1D13506 memory block is tagged as non-cacheable. This ensures the MPC821 does not attempt to cache any data read from, or written to, the S1D13506 or its display buffer.

```assembly
BR4 equ $120 ; CS4 base register
OR4 equ $124 ; CS4 option register
MemStart equ $40 ; upper word of S1D13506 start address
DisableReg equ $1 ; address of S1D13506 Disable Register
RevCodeReg equ $0 ; address of Revision Code Register

Start mfspr r1,IMMR ; get base address of internal registers
   andis. r1,r1,$ffff ; clear lower 16 bits to 0
   andis. r2,r0,0 ; clear r2
   oris r2,r2,MemStart ; write base address
   ori r2,r2,$0801 ; port size 16 bits; select GPCM; enable
   stw r2,OR4(r1) ; write to option register
   andis. r2,r0,0 ; clear r2
   oris r2,r2,$ffc0 ; address mask – use upper 10 bits
   ori r2,r2,$0608 ; normal CS negation; delay CS ¼ clock;
                   ; no burst inhibit (13506 does this)
   stw r2,OR4(r1) ; write to option register
   andis. r1,r0,0 ; clear r1
   oris r1,r1,MemStart ; point r1 to start of S1D13506 mem space
   stb r1,DisableReg(r1) ; write 0 to disable register

Loop lbz r0,RevCodeReg(r1) ; read revision code into r1
   b Loop ; branch forever

end
```

Note
MPC8BUG does not support comments or symbolic equates; these have been added for clarity.
5 Software

Test utilities and Windows® CE display drivers are available for the S1D13506. Full source code is available for both the test utilities and the drivers.

The test utilities are configurable for different panel types using a program called 13506CFG, or by directly modifying the source. The Windows CE display drivers can be customized by the OEM for different panel types, resolutions and color depths only by modifying the source.

The S1D13506 test utilities and Windows CE display drivers are available from your sales support contact or on the internet at http://www.eea.epson.com.

1 Introduction

This application note describes the hardware and software environment necessary to provide an interface between the S1D13506 Color LCD/CRT Controller and the Philips MIPS PR31500/PR31700 Processor.

The designs described in this document are presented only as examples of how such interfaces might be implemented. This application note will be updated as appropriate. Please check the Epson Electronics America website at http://www.eea.epson.com for the latest revision of this document before beginning any development.

We appreciate your comments on our documentation. Please contact us via email at techpubs@erd.epson.com.
2 Interfacing to the PR31500/PR31700

The Philips MIPS PR31500/PR31700 processor supports up to two PC Card (PCMCIA) slots. It is through this Host Bus Interface that the S1D13506 connects to the PR31500/PR31700 processor.

The S1D13506 can be successfully interfaced using one of the following configurations:

- Direct connection to the PR31500/PR31700 (see Section 4, “Direct Connection to the Philips PR31500/PR31700” on page 11).
- System design using the ITE IT8368E PC Card/GPIO buffer chip (see Section 5, “System Design Using the IT8368E PC Card Buffer” on page 14).
3 S1D13506 Host Bus Interface

The S1D13506 implements a 16-bit Host Bus Interface specifically for interfacing to the PR31500/PR31700 microprocessor.

The PR31500/PR31700 Host Bus Interface is selected by the S1D13506 on the rising edge of RESET#. After releasing reset, the bus interface signals assume their selected configuration. For details on S1D13506 configuration, see Section 4.2, “S1D13506 Configuration” on page 12.

Note

At reset, the Register/Memory Select bit in the Miscellaneous Register (REG[001h] bit 7) is set to 1. This means that only REG[000h] (read-only) and REG[001h] are accessible until a write to REG[001h] sets bit 7 to 0 making all registers accessible. When debugging a new hardware design, this can sometimes give the appearance that the interface is not working, so it is important to remember to clear this bit before proceeding with debugging.

3.1 PR31500/PR31700 Host Bus Interface Pin Mapping

3.2 PR31500/PR31700 Host Bus Interface Signals

When the S1D13506 is configured to operate with the PR31500/PR31700, the Host Bus Interface requires the following signals:

- **BUSCLK** is a clock input required by the S1D13506 Host Bus Interface. It is separate from the input clock (CLKI) and should be driven by the PR31500/PR31700 bus clock output DCLKOUT.

- Address input **AB20** corresponds to the PR31500/PR31700 signal ALE (address latch enable) whose falling edge indicates that the most significant bits of the address are present on the multiplexed address bus (AB[12:0]).

- Address input **AB19** should be connected to the PR31500/PR31700 signal /CARDREG. This signal is active when either IO or configuration space of the PR31500/PR31700 PC Card slot is being accessed.

- Address input **AB18** should be connected to the PR31500/PR31700 signal /CARDIORD. Either AB18 or the RD# input must be asserted for a read operation to take place.

- Address input **AB17** should be connected to the PR31500/PR31700 signal /CARDIOWR. Either AB17 or the WE0# input must be asserted for a write operation to take place.

- Address inputs **AB[16:13]** and control inputs M/R#, CS# and BS# must be tied to VDD as they are not used in this interface mode.

- Address inputs **AB[12:0]**, and the data bus **DB[15:0]**, connect directly to the PR31500/PR31700 address and data bus, respectively. MD4 must be set to select the proper endian mode on reset (see Section 4.2, “S1D13506 Configuration” on page 12). Because of the PR31500/PR31700 data bus naming convention and endian mode, S1D13506 DB[15:8] must be connected to PR31500/PR31700 D[23:16], and S1D13506 DB[7:0] must be connected to PR31500/PR31700 D[31:24].

- Control inputs **WE1#** and **RD/WR#** should be connected to the PR31500/PR31700 signals /CARDxCSH and /CARDxCSL respectively for byte steering.

- Input **RD#** should be connected to the PR31500/PR31700 signal /RD. Either RD# or the AB18 input (/CARDIORD) must be asserted for a read operation to take place.

- Input **WE0#** should be connected to the PR31500/PR31700 signal /WR. Either WE0# or the AB17 input (/CARDIOWR) must be asserted for a write operation to take place.

- **WAIT#** is a signal output from the S1D13506 that indicates the host CPU must wait until data is ready (read cycle) or accepted (write cycle) on the host bus. Since the host CPU accesses to the S1D13506 may occur asynchronously to the display update, it is possible that contention may occur in accessing the S1D13506 internal registers and/or display buffer. The WAIT# line resolves these contentions by forcing the host to wait until the resource arbitration is complete.
4 Direct Connection to the Philips PR31500/PR31700

The S1D13506 was specifically designed to support the Philips MIPS PR31500/PR31700 processor. When configured, the S1D13506 will utilize one of the PC Card slots supported by the processor.

4.1 Hardware Description

In this example implementation, the S1D13506 occupies one PC Card slot and resides in the Attribute and IO address range. The processor provides address bits A[12:0], with A[23:13] being multiplexed and available on the falling edge of ALE. Peripherals requiring more than 8K bytes of address space would require an external latch for these multiplexed bits. However, the S1D13506 has an internal latch specifically designed for this processor making additional logic unnecessary. To further reduce the need for external components, the S1D13506 has an optional BUSCLK divide-by-2 feature, allowing the high speed DCLKOUT from the processor to be directly connected to the BUSCLK input of the S1D13506. An optional external oscillator may be used for BUSCLK since the S1D13506 will accept host bus control signals asynchronously with respect to BUSCLK.

The following diagram shows a typical implementation of the interface.

Note: When connecting the S1D13506 RESET# pin, the system designer should be aware of all conditions that may reset the S1D13506 (e.g. CPU reset can be asserted during wake-up from power-down modes, or during debug states).

Figure 4-1: Typical Implementation of Direct Connection
The host interface control signals of the S1D13506 are asynchronous with respect to the S1D13506 bus clock. This gives the system designer full flexibility to choose the appropriate source (or sources) for CLKI and BUSCLK. The choice of whether both clocks should be the same, whether to use DCLKOUT as clock source, and whether an external or internal clock divider is needed, should be based on the desired:

- pixel and frame rates.
- power budget.
- part count.
- maximum S1D13506 clock frequencies.

The S1D13506 also has internal CLKI dividers providing additional flexibility.

### 4.2 S1D13506 Configuration

The S1D13506 latches MD15 through MD0 to allow selection of the bus mode and other configuration data on the rising edge of RESET#. For details on configuration, refer to the *S1D13506 Hardware Functional Specification*, document number X25B-A-001-xx.

The table below shows those configuration settings relevant to the Philips PR31500/PR31700 Host Bus Interface.

*Table 4-1: S1D13506 Configuration for Direct Connection*

= configuration for Philips PR31500/PR31700 Host Bus Interface
4.3 Memory Mapping and Aliasing

The PR31500/PR31700 uses a portion of the PC Card Attribute and IO space to access the S1D13506. The S1D13506 responds to both PC Card Attribute and IO bus accesses, thus freeing the programmer from having to set the PR31500/PR31700 Memory Configuration Register 3 bit CARD1IIOEN (or CARD2IIOEN if slot 2 is used). As a result, the PR31500/PR31700 sees the S1D13506 on its PC Card slot as described in the table below.

5 System Design Using the IT8368E PC Card Buffer

In a system design using one or two ITE IT8368E PC Card and multiple-function IO buffers, the S1D13506 can be interfaced so as to share one of the PC Card slots.

5.1 Hardware Description

The IT8368E can be programmed to allocate the same portion of the PC Card Attribute and IO space to the S1D13506 as in the direct connection implementation described in Section 4, “Direct Connection to the Philips PR31500/PR31700” on page 11.

Following is a block diagram showing an implementation using the IT8368E PC Card buffer.

![Figure 5-1: IT8368E Implementation Block Diagram](image-url)
5.2 IT8368E Configuration

The ITE IT8368E has been specifically designed to support EPSON LCD/CRT controllers. Older EPSON Controllers not supporting a direct interface to the Philips processor can utilize the IT8368E MFIO pins to provide the necessary control signals, however when using the S1D13506 this is not necessary as the Direct Connection described in Section 4, “Direct Connection to the Philips PR31500/PR31700” on page 11 can be used.

The IT8368E must have both “Fix Attribute/IO” and “VGA” modes enabled. When both these modes are enabled a 16M byte portion of the system PC Card attribute and IO space is allocated to address the S1D13506.

When the IT8368E senses that the S1D13506 is being accessed, it does not propagate the PC Card signals to its PC Card device. This makes S1D13506 accesses transparent to any PC Card device connected to the same slot.

For mapping details, refer to Section 4.3, “Memory Mapping and Aliasing” on page 13. For further information on configuring the IT8368E, refer to the IT8368E PC Card/GPIO Buffer Chip Specification.

5.3 S1D13506 Configuration

For S1D13506 configuration, refer to Section 4.2, “S1D13506 Configuration” on page 12.
6 Software

Test utilities and Windows® CE v2.0 display drivers are available for the S1D13506. Full source code is available for both the test utilities and the drivers.

The test utilities are configurable for different panel types using a program called 13506CFG, or by directly modifying the source. The Windows CE v2.0 display drivers can be customized by the OEM for different panel types, resolutions and color depths only by modifying the source.

The S1D13506 test utilities and Windows CE v2.0 display drivers are available from your sales support contact or on the internet at http://www.eea.epson.com.

1 Introduction

This application note describes the hardware and software environment necessary to provide an interface between the S1D13506 Color LCD/CRT/TV Controller and the Toshiba MIPS TX3912 Processor.

The designs described in this document are presented only as examples of how such interfaces might be implemented. This application note will be updated as appropriate. Please check the Epson Electronics America website at http://www.eea.epson.com for the latest revision of this document before beginning any development.

We appreciate your comments on our documentation. Please contact us via email at techpubs@erd.epson.com.
2 Interfacing to the TX3912

The Toshiba MIPS TX3912 processor supports up to two PC Card (PCMCIA) slots. It is through this Host Bus Interface that the S1D13506 connects to the TX3912 processor.

The S1D13506 can be successfully interfaced using one of the following configurations:

- Direct connection to the TX3912 (see Section 4, “Direct Connection to the Toshiba TX3912” on page 11).

- System design using the ITE IT8368E PC Card/GPIO buffer chip (see Section 5, “System Design Using the IT8368E PC Card Buffer” on page 14).
3 S1D13506 Host Bus Interface

The S1D13506 implements a 16-bit Host Bus Interface specifically for interfacing to the TX3912 microprocessor.

The TX3912 Host Bus Interface is selected by the S1D13506 on the rising edge of RESET#. After releasing reset, the bus interface signals assume their selected configuration. For details on S1D13506 configuration, see Section 4.2, “S1D13506 Configuration” on page 12.

Note
At reset, the Register/Memory Select bit in the Miscellaneous Register (REG[001h] bit 7) is set to 1. This means that only REG[000h] (read-only) and REG[001h] are accessible until a write to REG[001h] sets bit 7 to 0 making all registers accessible. When debugging a new hardware design, this can sometimes give the appearance that the interface is not working, so it is important to remember to clear this bit before proceeding with debugging.

3.1 TX3912 Host Bus Interface Pin Mapping

3.2 TX3912 Host Bus Interface Signals

When the S1D13506 is configured to operate with the TX3912, the Host Bus Interface requires the following signals:

- **BUSCLK** is a clock input required by the S1D13506 Host Bus Interface. It is separate from the input clock (CLKI) and should be driven by the TX3912 bus clock output DCLKOUT.

- Address input AB20 corresponds to the TX3912 signal ALE (address latch enable) whose falling edge indicates that the most significant bits of the address are present on the multiplexed address bus (AB[12:0]).

- Address input AB19 should be connected to the TX3912 signal CARDREG*. This signal is active when either IO or configuration space of the TX3912 PC Card slot is being accessed.

- Address input AB18 should be connected to the TX3912 signal CARDIORD*. Either AB18 or the RD# input must be asserted for a read operation to take place.

- Address input AB17 should be connected to the TX3912 signal CARDIOWR*. Either AB17 or the WE0# input must be asserted for a write operation to take place.

- Address inputs AB[16:13] and control inputs M/R#, CS# and BS# must be tied to VDD as they are not used in this interface mode.

- Address inputs AB[12:0], and the data bus DB[15:0], connect directly to the TX3912 address and data bus, respectively. MD4 must be set to select the proper endian mode on reset (see Section 4.2, “S1D13506 Configuration” on page 12). Because of the TX3912 data bus naming convention and endian mode, S1D13506 DB[15:8] must be connected to TX3912 D[23:16], and S1D13506 DB[7:0] must be connected to TX3912 D[31:24].

- Control inputs WE1# and RD/WR# should be connected to the TX3912 signals CARDxCSH* and CARDxCSL* respectively for byte steering.

- Input RD# should be connected to the TX3912 signal RD*. Either RD# or the AB18 input (CARDIORD*) must be asserted for a read operation to take place.

- Input WE0# should be connected to the TX3912 signal WR*. Either WE0# or the AB17 input (CARDIOWR*) must be asserted for a write operation to take place.

- **WAIT#** is a signal output from the S1D13506 that indicates the TX3912 must wait until data is ready (read cycle) or accepted (write cycle) on the host bus. Since the TX3912 accesses to the S1D13506 may occur asynchronously to the display update, it is possible that contention may occur in accessing the S1D13506 internal registers and/or display buffer. The WAIT# line resolves these contentions by forcing the host to wait until the resource arbitration is complete.
4 Direct Connection to the Toshiba TX3912

The S1D13506 was specifically designed to support the Toshiba MIPS TX3912 processor. When configured, the S1D13506 will utilize one of the PC Card slots supported by the processor.

4.1 Hardware Description

In this example implementation, the S1D13506 occupies one PC Card slot and resides in the Attribute and IO address range. The processor provides address bits A[12:0], with A[23:13] being multiplexed and available on the falling edge of ALE. Peripherals requiring more than 8K bytes of address space would require an external latch for these multiplexed bits. However, the S1D13506 has an internal latch specifically designed for this processor making additional logic unnecessary. To further reduce the need for external components, the S1D13506 has an optional BUSCLK divide-by-2 feature, allowing the high speed DCLKOUT from the processor to be directly connected to the BUSCLK input of the S1D13506. An optional external oscillator may be used for BUSCLK since the S1D13506 will accept host bus control signals asynchronously with respect to BUSCLK.

The following diagram shows a typical implementation of the interface.

![Diagram](image-url)

Note: When connecting the S1D13506 RESET# pin, the system designer should be aware of all conditions that may reset the S1D13506 (e.g. CPU reset can be asserted during wake-up from power-down modes, or during debug states).

*Figure 4-1: Typical Implementation of Direct Connection*
The host interface control signals of the S1D13506 are asynchronous with respect to the S1D13506 bus clock. This gives the system designer full flexibility to choose the appropriate source (or sources) for CLKI and BUSCLK. The choice of whether both clocks should be the same, whether to use DCLKOUT as clock source, and whether an external or internal clock divider is needed, should be based on the desired:

- pixel and frame rates.
- power budget.
- part count.
- maximum S1D13506 clock frequencies.

The S1D13506 also has internal CLKI dividers providing additional flexibility.

### 4.2 S1D13506 Configuration

The S1D13506 latches MD15 through MD0 to allow selection of the bus mode and other configuration data on the rising edge of RESET#. For details on configuration, refer to the *S1D13506 Hardware Functional Specification*, document number X25B-A-001-xx.

The table below shows those configuration settings relevant to the Toshiba TX3912 Host Bus Interface.

**Table 4-1: S1D13506 Configuration for Direct Connection**

= configuration for Toshiba TX3912 Host Bus Interface
4.3 Memory Mapping and Aliasing

The TX3912 uses a portion of the PC Card Attribute and IO space to access the S1D13506. The S1D13506 responds to both PC Card Attribute and IO bus accesses, thus freeing the programmer from having to set the TX3912 Memory Configuration Register 3 bit CARD1IOEN (or CARD2IOEN if slot 2 is used). As a result, the TX3912 sees the S1D13506 on its PC Card slot as described in the table below.

5 System Design Using the IT8368E PC Card Buffer

In a system design using one or two ITE IT8368E PC Card and multiple-function IO buffers, the S1D13506 can be interfaced so as to share one of the PC Card slots.

5.1 Hardware Description

The IT8368E can be programmed to allocate the same portion of the PC Card Attribute and IO space to the S1D13506 as in the direct connection implementation described in Section 4, “Direct Connection to the Toshiba TX3912” on page 11.

Following is a block diagram showing an implementation using the IT8368E PC Card buffer.

![Figure 5-1: IT8368E Implementation Block Diagram](image-url)
5.2 IT8368E Configuration

The ITE IT8368E has been specifically designed to support EPSON LCD/CRT controllers. Older EPSON Controllers not supporting a direct interface to the Toshiba processor can utilize the IT8368E MFIO pins to provide the necessary control signals, however when using the S1D13506 this is not necessary as the Direct Connection described in Section 4, “Direct Connection to the Toshiba TX3912” on page 11 can be used.

The IT8368E must have both “Fix Attribute/IO” and “VGA” modes enabled. When both these modes are enabled a 16M byte portion of the system PC Card attribute and IO space is allocated to address the S1D13506.

When the IT8368E senses that the S1D13506 is being accessed, it does not propagate the PC Card signals to its PC Card device. This makes S1D13506 accesses transparent to any PC Card device connected to the same slot.

For mapping details, refer to Section 4.3, “Memory Mapping and Aliasing” on page 13. For further information on configuring the IT8368E, refer to the IT8368E PC Card/GPIO Buffer Chip Specification.

5.3 S1D13506 Configuration

For S1D13506 configuration, refer to Section 4.2, “S1D13506 Configuration” on page 12.
6 Software

Test utilities and Windows® CE v2.0 display drivers are available for the S1D13506. Full source code is available for both the test utilities and the drivers.

The test utilities are configurable for different panel types using a program called 13506CFG, or by directly modifying the source. The Windows CE v2.0 display drivers can be customized by the OEM for different panel types, resolutions and color depths only by modifying the source.

The S1D13506 test utilities and Windows CE v2.0 display drivers are available from your sales support contact or on the internet at http://www.eea.epson.com.

2 Interfacing to the NEC VR4121

2.1 The NEC VR4121 System Bus

The VR-Series family of microprocessors features a high-speed synchronous system bus typical of modern microprocessors. Designed with external LCD controller support and Windows CE based embedded consumer applications in mind, the VR4121 offers a highly integrated solution for portable systems. This section provides an overview of the operation of the CPU bus in order to establish interface requirements.

2.1.1 Overview

The NEC VR4121 is designed around the RISC architecture developed by MIPS. This microprocessor is based on the 166MHz VR4120 CPU core which supports 64-bit processing. The CPU communicates with the Bus Control Unit (BCU) using its internal SysAD bus. The BCU in turn communicates with external devices using its ADD and DATA buses which can be dynamically sized to 16 or 32-bit operation.

The NEC VR4121 has direct support for an external LCD controller. Specific control signals are assigned for an external LCD controller providing an easy interface to the CPU. A 16M byte block of memory is assigned for the LCD controller and its own chip select and ready signals are available. Word or byte accesses are controlled by the system high byte signal (SHB#).
2.1.2 LCD Memory Access Cycles

Once an address in the LCD block of memory is placed on the external address bus (ADD[25:0]), the LCD chip select (LCDCS#) is driven low. The read or write enable signals (RD# or WR#) are driven low for the appropriate cycle and LCDRDY is driven low to insert wait states into the cycle. The high byte enable (SHB#) in conjunction with address bit 0 allows for byte steering.

The following figure illustrates typical NEC VR4121 memory read and write cycles to the LCD controller interface.

![Figure 2-1: NEC VR4121 Read/Write Cycles](image-url)
3 S1D13506 Host Bus Interface

The S1D13506 directly supports multiple processors. The S1D13506 implements a 16-bit MIPS/ISA Host Bus Interface which is most suitable for direct connection to the VR4121 microprocessor.

The MIPS/ISA Host Bus Interface is selected by the S1D13506 on the rising edge of RESET#. After releasing reset the bus interface signals assume their selected configuration. For details on S1D13506 configuration, see Section 4.2, “S1D13506 Configuration” on page 13.

**Note**

At reset, the Register/Memory Select bit in the Miscellaneous Register (REG[001h] bit 7) is set to 1. This means that only REG[000h] (read-only) and REG[001h] are accessible until a write to REG[001h] sets bit 7 to 0 making all registers accessible. When debugging a new hardware design, this can sometimes give the appearance that the interface is not working, so it is important to remember to clear this bit before proceeding with debugging.

3.1 Host Bus Interface Pin Mapping

3.2 Host Bus Interface Signal Descriptions

The S1D13506 MIPS/ISA Host Bus Interface requires the following signals.

- **BUSCLK** is a clock input which is required by the S1D13506 Host Bus Interface. It is separate from the input clock (CLKI) and is typically driven by the host CPU system clock.

- The address inputs AB[20:0], and the data bus DB[15:0], connect directly to the VR4121 address (ADD[20:0]) and data bus (DAT[15:0]), respectively. MD4 must be set to select the proper endian mode upon reset.

- **M/R#** (memory/register) selects between memory or register access. It may be connected to an address line, allowing system address ADD21 to be connected to the M/R# line.

- Chip Select (CS#) must be driven low by LCDCS# whenever the S1D13506 is accessed by the VR4121.

- **WE1#** connects to SHB# (the high byte enable signal from the VR4121) which in conjunction with address bit 0 allows byte steering of read and write operations.

- **WE0#** connects to WR# (the write enable signal from the VR4121) and must be driven low when the VR4121 bus is writing data to the S1D13506.

- **RD#** connects to RD# (the read enable signal from the VR4121) and must be driven low when the VR4121 bus is reading data from the S1D13506.

- **WAIT#** connects to LCDRDY and is a signal output from the S1D13506 that indicates the VR4121 bus must wait until data is ready (read cycle) or accepted (write cycle) on the host bus. Since VR4121 bus accesses to the S1D13506 may occur asynchronously to the display update, it is possible that contention may occur in accessing the S1D13506 internal registers and/or display buffer. The WAIT# line resolves these contentions by forcing the host to wait until the resource arbitration is complete.

- The **BS#** and **RD/WR#** signals are not used for the MIPS/ISA Host Bus Interface and should be tied high (connected to $V_{DD}$).
4 VR4121 to S1D13506 Interface

4.1 Hardware Description

The NEC VR4121 microprocessor is specifically designed to support an external LCD controller. It provides all the necessary internal address decoding and control signals required by the S1D13506.

The diagram below shows a typical implementation utilizing the S1D13506.

![Diagram of VR4121 to S1D13506 Interface]

Note:
When connecting the S1D13506 RESET# pin, the system designer should be aware of all conditions that may reset the S1D13506 (e.g., CPU reset can be asserted during wake-up from power-down modes, or during debug states).

Figure 4-1: NEC VR4121 to S1D13506 Configuration Schematic

Note
For pin mapping see Table 3-1: “Host Bus Interface Pin Mapping,” on page 10.
4.2 S1D13506 Configuration

The S1D13506 latches MD15 through MD0 to allow selection of the bus mode and other configuration data on the rising edge of RESET#. For details on configuration, refer to the *S1D13506 Hardware Functional Specification*, document number X25B-A-001-xx.

The table below shows those configuration settings relevant to the MIPS/ISA Host Bus Interface used by the NEC VR4121 microprocessor.

*Table 4-1: Summary of Power-On/Reset Options*

= configuration for NEC VR4121 microprocessor

4.3 NEC VR4121 Configuration

The NEC VR4121 register BCUCNTREG1 bit ISAM/LCD must be set to 0. A 0 indicates that the reserved address space is for the LCD controller, and not for the high-speed ISA memory. The register BCUCNTREG2 bit GMODE must be set to 1 to indicate that a non-inverting data bus is used for LCD controller accesses.

The LCD interface must be set to operate using a 16-bit data bus. This is accomplished by setting the NEC VR4121 register BCUCNTREG3 bit LCD32/ISA32 to 0.

**Note**

Setting the register BCUCNTREG3 bit LCD32/ISA32 to 0 affects both the LCD controller and high-speed ISA memory access.

The frequency of BUSCLK output is programmed from the state of pins TxD/CLKSEL2, RTS#/CLKSEL1 and DTR#/CLKSEL0 during reset, and from the PMU (Power Management Unit) configuration registers of the NEC VR4121. The S1D13506 works at any of the frequencies provided by the NEC VR4121.
4.4 Memory Mapping and Aliasing

The NEC VR4121 provides the internal address decoding required by an external LCD controller. The physical address range from 0A00 0000h to 0AFF FFFFh (16M bytes) is reserved for use by an external LCD controller (e.g. S1D13506).

The S1D13506 supports up to 2M bytes of display buffer. The NEC VR4121 address line ADD21 (connected to M/R#) is used to select between the S1D13506 display buffer (ADD21=1) and the S1D13506 internal registers (ADD21=0). NEC VR4121 address lines ADD[23:22] are ignored, thus the S1D13506 is aliased four times at 4M byte intervals over the LCD controller address range. Address lines ADD[25:24] are set at 10b and never change while the LCD controller is being addressed.
5 Software

Test utilities and Windows® CE v2.0 display drivers are available for the S1D13506. Full source code is available for both the test utilities and the drivers.

The test utilities are configurable for different panel types using a program called 13506CFG, or by directly modifying the source. The Windows CE v2.0 display drivers can be customized by the OEM for different panel types, resolutions and color depths only by modifying the source.

The S1D13506 test utilities and Windows CE v2.0 display drivers are available from your sales support contact or on the internet at http://www.eea.epson.com.

1 Introduction

This application note describes the hardware and software environment required to provide an interface between the S1D13506 Color LCD/CRT/TV Controller and the NEC V832™ microprocessor (µPD705102).

The designs described in this document are presented only as examples of how such interfaces might be implemented. This application note is updated as appropriate. Please check the Epson Electronics America Website at http://www.eea.epson.com for the latest revision of this document before beginning any development.

We appreciate your comments on our documentation. Please contact us via email at documentation@erd.epson.com.
2 Interfacing to the NEC V832

2.1 The NEC V832 System Bus

This section provides an overview of the operation of the CPU bus in order to establish interface requirements.

2.1.1 Overview

The NEC V832 is designed around the RISC architecture developed by MIPS. This microprocessor is based on the 32-bit V830 CPU core. The CPU communicates with external devices via the Bus Control Unit (BCU). The BCU in turn communicates using its ADD and DATA buses which can be dynamically sized to 16 or 32-bit operation.

The NEC V832 features dedicated chip select pins which allow memory-mapped IO operations. A 16M byte block of addressing space can be assigned for the LCD controller and its own chip select and ready signals are available. Word or byte accesses are controlled by system byte enable signals (LLBEN and LUBEN).
2.1.2 Access Cycles

Once an address in the appropriate range is placed on the external address bus (A[23:1]), the corresponding chip select (CSn) is driven low. The read or write enable signals (IORD or IOWR) are driven low and READY is driven low by the S1D13506 to insert wait states into the cycle. The byte enable signals (LLBEN and LUBEN) allow byte steering.

The following figure illustrates typical NEC V832 memory-mapped IO access cycles.

![NEC V832 Read/Write Cycles](image-url)
3 S1D13506 Host Bus Interface

The S1D13506 directly supports multiple processors. The S1D13506 implements a 16-bit PC Card (PCMCIA) Host Bus Interface which is most suitable for direct connection to the V832 microprocessor.

The PC Card Host Bus Interface is selected by the S1D13506 on the rising edge of RESET#. After releasing reset the bus interface signals assume their selected configuration. For details on S1D13506 configuration, see Section 4.2, “S1D13506 Hardware Configuration” on page 13.

**Note**
At reset, the Register/Memory Select bit in the Miscellaneous Register (REG[001h] bit 7) is set to 1. This means that only REG[000h] (read-only) and REG[001h] are accessible until a write to REG[001h] sets bit 7 to 0 making all registers accessible. When debugging a new hardware design, this can sometimes give the appearance that the interface is not working, so it is important to remember to clear this bit before proceeding with debugging.

</tr>
</tbody>
</table>

**Note**
1 The bus signal A0 is not used by the S1D13506 internally.
3.2 Host Bus Interface Signal Descriptions

The S1D13506 PC Card Host Bus Interface requires the following signals.

- BUSCLK is a clock input which is required by the S1D13506 Host Bus Interface. It is driven by the V832 signal SDCLKOUT.

- The address inputs AB[20:1], and the data bus DB[15:0], connect directly to the V832 address (A[20:1]) and data bus (D[15:0]), respectively. MD4 must be set to select little endian mode upon reset.

- M/R# (memory/register) selects between memory or register access. It may be connected to an address line, allowing system address A21 to be connected to the M/R# line.

- Chip Select (CS#) must be driven low by CSx (where x is the V832 chip select used) whenever the S1D13506 is accessed by the V832.

- WE1# and RD/WR# connect to LUBEN and LLBEN (the byte enables for the high-order and low-order bytes). They are driven low when the V832 is accessing the S1D13506.

- RD# connects to IORD (the read enable signal from the V832).

- WE0# connects to IOWR (the write enable signal from the V832).

- WAIT# is a signal output from the S1D13506 that indicates the V832 must wait until data is ready (read cycle) or accepted (write cycle) on the host bus. Since V832 accesses to the S1D13506 may occur asynchronously to the display update, it is possible that contention may occur in accessing the S1D13506 internal registers and/or display buffer. The WAIT# line resolves these contentions by forcing the host to wait until the resource arbitration is complete. For V832 applications, this signal should be set active low using the MD5 configuration input.

- The Bus Start (BS#) signal is not used for the PC Card Host Bus Interface and should be tied high (connected to VDD).

- The RESET# (active low) input of the S1D13506 may be connected to the system RESET.
4 V832 to S1D13506 Interface

4.1 Hardware Description

The NEC V832 microprocessor features configurable chip select lines which can easily be used for an external LCD controller. It provides all the necessary internal address decoding and control signals required by the S1D13506.

The diagram below shows a typical implementation utilizing the S1D13506.

Note: When connecting the S1D13506 RESET# pin, the system designer should be aware of all conditions that may reset the S1D13506 (e.g. CPU reset can be asserted during wake-up from power-down modes, or during debug states).

Figure 4-1: NEC V832 to S1D13506 Configuration Schematic

Note
For pin mapping see Table 3-1: “Host Bus Interface Pin Mapping,” on page 10.
4.2 S1D13506 Hardware Configuration

The S1D13506 latches MD15 through MD0 to allow selection of the bus mode and other configuration data on the rising edge of RESET#. For details on configuration, refer to the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx.

The table below shows those configuration settings relevant to the PC Card Host Bus Interface used by the NEC V832 microprocessor.

Table 4-1: Summary of Power-On/Reset Options

= configuration for NEC V832 microprocessor
4.3 NEC V832 Configuration

The NEC V832 should access the S1D13506 in non-burst mode only. This is ensured by using any one of the CS3 to CS6 lines to control the S1D13506 and setting that line to respond to IO operations using the NEC V832 BCTC register. For example, if line CS5 is used then bit 5 (CT5) of the BCTC register should be set to 1 (IO cycle).

The NEC V832 data bus should be programmed to use 16 bits as the maximum width for S1D13506 bus transactions. This does not affect the width of other NEC V832 data bus transactions. Data bus width is set in the NEC V832 DBC register. For example, if line CS4 is used then bit 4 (BW4) of the DBC register should be set to 1 (16-bit bus width).

Depending on bus clock frequencies, a different number of wait states may be required. These need to be programmed into the NEC V832 PWC0 and PWC1 registers in the bit field corresponding to the CSn line chosen for the S1D13506. For example, if CS3 is used and one wait state is required, then bits 14-12 of the NEC V832 PWC0 register (WS3) must be set to 001b (one wait state). If CS6 is used and no wait state is needed, then bits 11-8 of the NEC V832 PWC1 register (WS6) must be set to 0000b (zero wait state).

The table below shows the recommended wait states depending on the bus clock frequency.

<table>
<thead>
<tr>
<th>Wait States</th>
<th>Maximum Frequency (SDCLKOUT)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>10.8MHz</td>
</tr>
<tr>
<td>1</td>
<td>32.6MHz</td>
</tr>
<tr>
<td>2</td>
<td>No limit</td>
</tr>
</tbody>
</table>

Table 4-2: NEC V832 Wait States vs. Bus Clock Frequency

No idle state needs to be added. The NEC V832 PIC0 and PIC1 register bit field corresponding to the CSn line chosen for the S1D13506 must be set to zero. For example, if CS3 is used then bits 14-12 of the NEC V832 PIC0 register (IS3) must be set to 000b (no idle state).
4.4 Memory Mapping and Aliasing

The CSn line selected determines the address range to be reserved for the S1D13506. The table below summarizes the S1D13506 address mapping.

<table>
<thead>
<tr>
<th>CSn Line</th>
<th>NEC V832 IO Address</th>
<th>S1D13506 Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>CS3</td>
<td>0300 0000h to 03FF FFFFh</td>
<td>0300 0000h Registers</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0320 0000h Display buffer (2M bytes)</td>
</tr>
<tr>
<td>CS4</td>
<td>0400 0000h to 04FF FFFFh</td>
<td>0400 0000h Registers</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0420 0000h Display buffer (2M bytes)</td>
</tr>
<tr>
<td>CS5</td>
<td>0500 0000h to 05FF FFFFh</td>
<td>0500 0000h Registers</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0520 0000h Display buffer (2M bytes)</td>
</tr>
<tr>
<td>CS6</td>
<td>0600 0000h to 06FF FFFFh</td>
<td>0600 0000h Registers</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0620 0000h Display buffer (2M bytes)</td>
</tr>
</tbody>
</table>

Each address range is 16M bytes, therefore, the S1D13506 is aliased four times over the address range.
5 Software

Test utilities and Windows® CE display drivers are available for the S1D13506. Full source code is available for both the test utilities and the drivers.

The test utilities are configurable for different panel types using a program called 13506CFG, or by directly modifying the source. The Windows CE display drivers can be customized by the OEM for different panel types, resolutions and color depths only by modifying the source.

The S1D13506 test utilities and Windows CE display drivers are available from your sales support contact or www.eea.epson.com.

1 Introduction

This application note describes the hardware and software environment required to provide an interface between the S1D13506 Color LCD/CRT/TV Controller and the Intel StrongARM SA-1110.

The designs described in this document are presented only as examples of how such interfaces might be implemented. This application note is updated as appropriate. Please check the Epson Electronics America website at http://www.eea.epson.com for the latest revision of this document before beginning any development.

We appreciate your comments on our documentation. Please contact us via email at documentation@erd.epson.com.
2 Interfacing to the StrongARM SA-1110 Bus

2.1 The StrongARM SA-1110 System Bus

The StrongARM SA-1110 microprocessor is a highly integrated communications microcontroller that incorporates a 32-bit StrongARM RISC processor core. The SA-1110 is ideally suited to interface to the S1D13506 LCD controller and provides a high performance, power efficient solution for embedded systems.

2.1.1 StrongARM SA-1110 Overview

The SA-1110 system bus can access both variable-latency IO and memory devices. The SA-1110 uses a 26-bit address bus and a 32-bit data bus which can be used to access 16-bit devices. A chip select module with six chip select signals (each accessing 64M bytes of memory) allows selection of external devices. Only chip selects 3 through 5 (nCS[5:3]) may be used to select variable-latency devices which use RDY to extend access cycles. These chip selects are individually programmed in the SA-1110 memory configuration registers and can be configured for either a 16 or 32-bit data bus.

Byte steering is implemented using the four signals nCAS[3:0]. Each signal selects a byte on the 32-bit data bus. For example, nCAS0 selects bits D[7:0] and nCAS3 selects bits D[31:24]. For a 16-bit data bus, only nCAS[1:0] are used with nCAS0 selecting the low byte and nCAS1 selecting the high byte. The SA-1110 can be configured to support little or big endian mode.

2.1.2 Variable-Latency IO Access Overview

A data transfer is initiated when a memory address is placed on the SA-1110 system bus and a chip select signal (nCS[5:3]) is driven low. If all byte enable signals (nCAS[3:0]) are driven low, then a 32-bit transfer takes place. If only nCAS[1:0] are driven low, then a word transfer takes place over a 16-bit bus interface. If only one byte enable is driven low, then a byte transfer takes place on the respective data lines.

During a read cycle, the output enable signal (nOE) is driven low. A write cycle is specified by driving nOE high and driving the write enable signal (nWE) low. The cycle can be lengthened by driving RDY high for the time needed to complete the cycle.
2.1.3 Variable-Latency IO Access Cycles

The first nOE assertion occurs two memory cycles after the assertion of chip select (nCS3, nCS4, or nCS5). Two memory cycles prior to the end of minimum nOE or nWE assertion (RDF+1 memory cycles), the SA-1110 starts sampling the data ready input (RDY). Samples are taken every half memory cycle until three consecutive samples (at the rising edge, falling edge, and following rising edge of the memory clock) indicate that the IO device is ready for data transfer. Read data is latched one-half memory cycle after the third successful sample (on falling edge). Then nOE or nWE is deasserted on the next rising edge and the address may change on the subsequent falling edge. Prior to a subsequent data cycle, nOE or nWE will remain deasserted for RDN+1 memory cycles. The chip select and byte selects (nCAS/DQM[1:0] for 16-bit data transfers), remain asserted for one memory cycle after the final nOE or nWE deassertion of the burst.

The SA-1110 is capable of burst cycles during which the chip select remains low while the read or write command is asserted, precharged and reasserted repeatedly.

Figure 2-1: illustrates a typical variable-latency IO access read cycle on the SA-1110 bus.

![Figure 2-1: SA-1110 Variable-Latency IO Read Cycle](image)
Figure 2-2: illustrates a typical variable-latency IO access write cycle on the SA-1110 bus.

Figure 2-2: SA-1110 Variable-Latency IO Write Cycle
3 S1D13506 Host Bus Interface

The S1D13506 directly supports multiple processors. The S1D13506 implements a 16-bit PC Card (PCMCIA) Host Bus Interface which is most suitable for direct connection to the SA-1110.

The PC Card Host Bus Interface is selected by the S1D13506 on the rising edge of RESET#. After releasing reset the bus interface signals assume their selected configuration. For details on S1D13506 configuration, see Section 4.2, “S1D13506 Hardware Configuration” on page 14.

**Note**

At reset, the Register/Memory Select bit in the Miscellaneous Register (REG[001h] bit 7) is set to 1. This means that only REG[000h] (read-only) and REG[001h] are accessible until a write to REG[001h] sets bit 7 to 0 making all registers accessible. When debugging a new hardware design, this can sometimes give the appearance that the interface is not working, so it is important to remember to clear this bit before proceeding with debugging.

3.1 Host Bus Interface Pin Mapping

The following table shows the functions of each Host Bus Interface signal.

<table>
<thead>
<tr>
<th>S1D13506 Pin Name</th>
<th>SA-1110</th>

</tbody>
</table>

**Note**

¹ The bus signal A0 is not used by the S1D13506 internally.
3.2 Host Bus Interface Signal Descriptions

The S1D13506 PC Card Host Bus Interface requires the following signals.

- BUSCLK is a clock input which is required by the S1D13506 Host Bus Interface. It is driven by one of the SA-1110 signals SDCLK1 or SDCLK2 (the example implementation in this document uses SDCLK2). For further information, see Section 4.3, “Performance” on page 14.

- The address inputs AB[20:1], and the data bus DB[15:0], connect directly to the SA-1110 address (A[20:1]) and data bus (D[15:0]), respectively. MD4 must be set to select little endian mode upon reset.

- M/R# (memory/register) selects between memory or register access. It may be connected to an address line, allowing system address A21 to be connected to the M/R# line.

- Chip Select (CS#) must be driven low by nCSx (where x is the SA-1110 chip select used) whenever the S1D13506 is accessed by the SA-1110.

- WE1# and RD/WR# connect to nCAS1 and nCAS0 (the byte enables for the high-order and low-order bytes). They are driven low when the SA-1110 is accessing the S1D13506.

- RD# connects to nOE (the read enable signal from the SA-1110).

- WE0# connects to nWE (the write enable signal from the SA-1110).

- WAIT# is a signal output from the S1D13506 that indicates the SA-1110 must wait until data is ready (read cycle) or accepted (write cycle) on the host bus. Since SA-1110 accesses to the S1D13506 may occur asynchronously to the display update, it is possible that contention may occur in accessing the S1D13506 internal registers and/or display buffer. The WAIT# line resolves these contentions by forcing the host to wait until the resource arbitration is complete. For the SA-1110, this signal should be set active low using the MD5 configuration input.

- The Bus Start (BS#) signal is not used for this Host Bus Interface and should be tied high (connected to VDD).

- The RESET# (active low) input of the S1D13506 may be connected to the system RESET.
4 StrongARM SA-1110 to S1D13506 Interface

4.1 Hardware Description

The S1D13506 is designed to directly support a variety of CPUs, providing an interface to each processor’s unique “local bus”. Using the S1D13506’s PC Card Host Bus Interface provides a “glueless” interface to the SA-1110.

In this implementation, the address inputs (AB[20:1]) and data bus (DB[15:0]) connect directly to the CPU address (A[20:1]) and data bus (D[15:0]). M/R# is treated as an address line so that it can be controlled using system address A21.

BS# (Bus Start) is not used and should be tied high (connected to VDD).

The following diagram shows a typical implementation of the SA-1110 to S1D13506 interface.

![Diagram showing the interface between SA-1110 and S1D13506](image)

Note: When connecting the S1D13506 RESET# pin, the system designer should be aware of all conditions that may reset the S1D13506 (e.g., CPU reset can be asserted during wake-up from power-down modes, or during debug states).

---

*Figure 4-1: Typical Implementation of SA-1110 to S1D13506 Interface*
4.2 S1D13506 Hardware Configuration

The S1D13506 latches MD15 through MD0 to allow selection of the bus mode and other configuration data on the rising edge of RESET#. For details on configuration, refer to the S1D13506 Hardware Functional Specification, document number X25B-A-001-xx.

The table below shows only those configuration settings important to the PC Card Host Bus Interface.

### Table 4-1: Summary of Power-On/Reset Options

</tbody>
</table>

= configuration for PC Card Host Bus Interface

4.3 Performance

The S1D13506 PC Card Interface specification supports a BUSCLK up to 50MHz, and therefore provides a high performance display solution.

The BUSCLK signal input to the S1D13506 (from one of the SDCLK[2:1] pins) is a derivative of the SA-1110 internal processor speed. Since the PC Card Host Bus Interface on the S1D13506 has a maximum BUSCLK of 50MHz, the output clock from the SA-1110 must be a divided down from the processor clock. The DRAM Refresh Control Register (MDREFR) determines the output of this signal.

- If SDCLK2 is used, bit 26 should be set to 1 to divide the CPU clock by 4.
- If SDCLK1 is used, bit 22 should be set to 1 to divide the CPU clock by 4.
4.4 Register/Memory Mapping

The S1D13506 is a memory mapped device. The SA-1110 will use the memory assigned to a chip select (nCS4 in this example) to map the S1D13506 internal registers and display buffer. The internal registers require 2M bytes of memory and are mapped to the lower memory address space starting at zero. The display buffer also requires 2M bytes and is mapped in the third and fourth megabytes (ranging from 200000h to 3FFFFFFh).

This implementation decodes as shown in the following table.

<table>
<thead>
<tr>
<th>M/R# (A21)</th>
<th>Address Range</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 - 1F FFFFh</td>
<td>Internal Registers</td>
</tr>
<tr>
<td>1</td>
<td>20 0000h - 3F FFFFh</td>
<td>Display Buffer</td>
</tr>
</tbody>
</table>

Each chip select on the SA-1110 provides 64M bytes of address space. Without further resolution of the decoding logic (M/R# connected to A21), the entire register set and display buffer are aliased for every 4M byte boundary within the specified address range of the chip select. Since address bits A[25:22] are ignored, the S1D13506 registers and display buffer are aliased 16 times.

**Note**
If aliasing is not desirable, the upper addresses must be fully decoded.
4.5 StrongARM SA-1110 Register Configuration

The SA-1110 requires configuration of several of its internal registers to interface to the S1D13506 PC Card Host Bus Interface.

- The Static Memory Control Registers (MSC[2:0]) are read/write registers containing control bits for configuring static memory or variable-latency IO devices. These registers correspond to chip select pairs nCS[5:4], nCS[3:2], and nCS[1:0] respectively. Each of the three registers contains two identical CNFG fields, one for each chip select within the pair. Since only nCS[5:3] controls variable-latency IO devices, MSC2 and MSC1 should be programmed based on the chip select used.

Parameter RTx<1:0> should be set to 01b (selects variable-latency IO mode).

Parameter RBWx should be set to 1 (selects 16-bit bus width).

Parameter RDFx<4:0> should be set according to the maximum desired CPU frequency as indicated in the table below.

Table 4-3: RDFx Parameter Value versus CPU Maximum Frequency

<table>
<thead>
<tr>
<th>CPU Frequency</th>
<th>RDFx</th>
</tr>
</thead>
<tbody>
<tr>
<td>147.5MHz</td>
<td>2</td>
</tr>
<tr>
<td>206.4MHz</td>
<td>3</td>
</tr>
<tr>
<td>Up to SA-1110</td>
<td>4</td>
</tr>
</tbody>
</table>

Parameter RDNx<4:0> should be set to 0 (minimum command precharge time).

Parameter RRRx<2:0> should be set to 0 (minimum nCSx precharge time).

- The S1D13506 endian mode is set to little endian. To program the SA-1110 for little endian as well use the control register (register 1).

- Bit 7 must be set to 0.

- The BUSCLK signal input to the S1D13506 (from one of the SDCLK[2:1] pins) is a derivative of the SA-1110 internal processor speed. Since the PC Card Host Bus Interface on the S1D13506 has a maximum BUSCLK of 50MHz, the output clock from the SA-1110 must be a divided down from the processor clock. The DRAM Refresh Control Register (MDREFR) determines the output of this signal.

If SDCLK2 is used, bit 26 should be set to 1 to divide the CPU clock by 4.

If SDCLK1 is used, bit 22 should be set to 1 to divide the CPU clock by 4.
5 Software

Test utilities and Windows® CE display drivers are available for the S1D13506. Full source code is available for both the test utilities and the drivers.

The test utilities are configurable for different panel types using a program called 13506CFG, or by directly modifying the source. The Windows CE display drivers can be customized by the OEM for different panel types, resolutions and color depths only by modifying the source.

The S1D13506 test utilities and Windows CE display drivers are available from your sales support contact or on the internet at http://www.eea.epson.com.
